*Functions of Bone Marrow in Some Forms of Chronic Hepatitis. M. Milela.—p. 1.

Bone Marrow in Chronic Hepatitis.—Milela reports microscopic observations on the bone marrow obtained by sternal puncture in 13 cases of chronic hepatitis. There were 4 cases of atrophic cirrhosis of the Laënnec type, 4 of syphilitic hepatitis, 1 of amebiasis of the liver, 1 of Hanot cirrhosis, 1 of Eppinger cirrhosis and 2 cases of chronic ascitogenic hypertrophy of the liver. Erythropoiesis was inadequate in all of the cases. The maturation of the erythrocytes was arrested at the level of the polychromatic phase. Anemia in chronic disease of the liver is apparently due to the toxic action of the diseased liver on the bone marrow.

*Acute Cerebral Edema and Mesencephalic Hemorrhages as Cause of Death in Metastatic Tumors. R. M. E. Carrea.—p. 228.

Acute Cerebral Edema.—Carrea points out the cause of death in intracranial hypertension due to metastatic cerebral tumors. There is either a mesencephalic hemorrhage from cisternal hernia or cisternal hernia alone. Mesencephalic hemorrhage is fatal, whereas cisternal hernia is curable. Cisternal hernia of the temporal lobe is frequent in cerebral tumors. It manifests itself by a sudden appearance of symptoms of acute cerebral edema leading to respiratory difficulty which may rapidly result in respiratory paralysis. Treatment consists in putting the patient to bed with the head at a lower level than the feet. Intravenous injection of hypertonic dextrose solution and continuous ventricle drainage or repeated evacuation by ventricular puncture and transfusions of human plasma are indicated. Hypertonic sodium chloride solution is contraindicated. Failure of the therapy calls for surgical intervention, either section of the neck of the hernia or temporal lobectomy. When respiratory failure occurs just before the operation, artificial respiration should be practiced as long as the heart beats. The author's patient died from an acute respiratory paralysis. The heart continued beating for about ten minutes. Death was due to acute cerebral edema with formation of a huge cisternal hernia at the temporal lobe and an associated mesencephalic hemorrhage.

*Erythroblastosis of Newborn Infants and Rh Factor. M. A. Etcheverry, H. Linares Garzón and J. C. Pereyra.—p. 93.

Erythroblastosis of Newborn Infants.—Etcheverry and his collaborators report observations on a family of 4 erythroblastotic infants. The young parents were apparently normal. The mother had three normal deliveries and an induced abortion. The first child was born with sclerema and had had convulsions from infancy. The 2 following infants died within one and two weeks after birth from acute jaundice and from acute hemolytic anemia. In the course of the fifth pregnancy it was established that the blood of the mother belonged to blood group A and was Rh negative, whereas that of the father and of the child belonged to blood groups O and A respectively and was Rh positive. Anti-Rh agglutinins were not present in the blood of the mother during the first months of pregnancy. They appeared about the eighth month of pregnancy and increased with such rapidity that it was necessary to induce labor near full term. The infant girl was born apparently normal. Her blood was of group A and was Rh positive. The blood of the umbilical cord showed strong reticulocytosis, highly increased indirect bilirubinemia and a scanty number of erythroblasts. Microscopic study of the placenta showed abnormal persistence of the Langhans layer, intraplacental hematoma with erythroblasts, erythroblasts in the chorionic vessels, and edema and hyperplasia of the chorionic villi. The infant exhibited jaundice three hours after birth. Transfusion with O-Rh negative blood in amounts varying between 20 and 50 cc. each was made four hours after birth and at intervals of twelve hours during the first week of life of the infant. She had fever during the first three days and splenomegaly. Jaundice became acute during the first week and then subsided. During the second week of life of the infant transfusion of O-Rh positive blood was administered by mistake. Immediately afterward the infant presented symptoms of acute anemia, which became grave in four days. The hemogram confirmed the diagnosis. The condition was controlled by transfusions of A-Rh negative blood. It was given first daily, then every other day and at longer intervals in doses of 50 to 180 cc. The infant was normal when discharged from the hospital at the age of 3 months. The authors direct attention to the meaning of sclerema in the newborn, which suggests erythroblastosis of the newborn in the family. They also point to the importance of blood transfusion in the therapy of erythroblastosis of newborn infants. Transfusion with Rh negative blood belonging to the O blood group or to the blood group of the infant should be administered.

Paroxysmal Paralytic Hemoglobinuria.—Louw and Nielsen found only 4 cases of paroxysmal paralytic myoglobinuria in the literature. Their case, the first in the Scandinavian literature, was in a boy aged 10, with history of repeated attacks of muscular pain and difficulty in walking since the age of 4, who was admitted for treatment during an acute attack. Spectroscopy showed excretion of myoglobin during the attack, when there was also pronounced creatinuria. The establishment of 8 cases of progressive muscular dystrophy in the boy's family suggests that this disorder and paralytic myoglobinuria may be different forms of the same condition, the latter representing the acute manifestation, the progressive muscular dystrophy the chronic form.

MEDIASTINAL EMPHYSEMA

THE FRANK BILLINGS LECTURE

LOUIS HAMMAN, M.D.
BALTIMORE

When I was a young physician Dr. Frank Billings was one of the most distinguished figures in American medicine. I looked on him with admiration and awe. Therefore, to be asked to give this lecture, founded to pefpetuate his memory, is not only an honor but also a source of great pleasure. My only regret is that I have not a more worthy tribute for the occasion.

The subject of mediastinal emphysema is not a new one. Occasional cases with dramatic symptoms were reported a century or longer ago. However, during the past twenty years, especially during the past decade, experimental investigation and clinical observation have extended our knowledge and put it on a firm base. The conditions causing mediastinal emphysema are now well known; the mechanism of its production and its relation to associated manifestations, chiefly interstitial emphysema of the lungs and pneumothorax, have been clearly exposed; the symptoms that result are better understood and therefore its recognition has become easy. It is true that in most instances mediastinal emphysema is a benign condition but, even so, it is important that the physician should not confuse it with serious diseases to which it may bear a close resemblance. However, not infrequently grave and threatening symptoms arise and then a correct appraisal of the situation and prompt action may be life saving. Therefore it may serve a useful purpose briefly to review the present state of our knowledge concerning this interesting and important condition.

PATHWAYS FOLLOWED BY AIR IN REACHING THE MEDIASTINUM

Air may reach the mediastinum by four routes: (1) along the fascial planes of the neck, (2) through a perforation of the trachea, bronchus or esophagus into the mediastinum, (3) from the retroperitoneal space and (4) from the interstitial tissues of the lung. Other channels have been suggested as possible routes, but that these routes are ever followed has not been demonstrated conclusively. These hypothetical routes are (*a*) dissection of air between the parietal pleura and the chest wall, (*b*) dissection of air beneath the visceral pleura and (*c*) the passage of air from the pleural cavity to the mediastinum.

That air may enter the mediastinum along the fascial planes of the neck seems to be satisfactorily established. During deep dissection of the tissues of the neck,[1] especially during thyroidectomy and tracheotomy, surgeons have described hearing air being sucked into the mediastinum. Since under these circumstances pneumothorax also often occurs, it has been suggested that the pneumothorax may precede the mediastinal emphysema, the pneumothorax being due to injury of the pleura where it protrudes into the neck above the clavicle. That this sequence of events actually occurs has never convincingly been demonstrated. At the postmortem examination of patients who have died of mediastinal emphysema following, for instance, thyroidectomy, no evidence of injury to the pleura has been discovered; whereas, in the frequently repeated experiments of blowing air into the mediastinum and of producing mediastinal emphysema by forceful inflation of the lungs, pneumothorax regularly occurs and at autopsy a minute rent may be found in the mediastinal pleura, or the surface of the mediastinal pleura may be studded with small saccular protrusions, suggesting that air had entered the pleural cavity through a rupture of one of these vesicles, even though the actual point of rupture cannot be located. It is now well established that mediastinal emphysema is usually the result of rupture of pulmonary alveoli with the production of interstitial emphysema of the lung. Since operations on the neck are always accompanied by conditions (anesthesia, tracheal or bronchial obstruction, coughing) which are the familiar precursors of interstitial emphysema of the lungs, it seems altogether likely that mediastinal emphysema following such operations is often, probably even usually, a sequence to rupture of alveoli rather than to the direct aspiration of air into the mediastinum. In any particular case it might be impossible to decide which of the two routes air had followed. As proving that in certain cases air had been directly aspirated, the fact is cited that at autopsy no evidence of interstitial emphysema of the lungs had been found. This evidence is not altogether conclusive, for the preexistence of interstitial emphysema may be overlooked unless the autopsy is performed with especial care.

Air entering the deep fascial planes of the neck at a higher point may dissect downward and enter the

mediastinum. After tonsillectomy subcutaneous emphysema in the neck may occur and occasionally mediastinal emphysema follows. I have observed this train of events after puncture and irrigation of the maxillary antrum. It may follow deep wounds of the neck and wounds of the pharynx and buccal cavity.

It is clear that rupture of the lower portion of the trachea or of one of the main bronchi will allow air freely to enter the mediastinal tissues. Such an accident occurs only rarely from disease or from trauma. It has happened after lobectomy and pneumonectomy. In the early period of operating on the lungs, before technical procedures had been perfected, it was difficult to close the severed bronchus securely. Occasionally air leaked into the mediastinum, always with disturbing, sometimes with serious, results. Better methods of closing the bronchus have almost eliminated the danger of this accident. No doubt at times air may enter the mediastinum through a perforation of the esophagus. However, when this accident occurs there is always infection, and the serious symptoms of infection obscure the lesser symptoms that may arise from a small amount of air entering the mediastinum.

Circumstances That Cause Interstitial Emphysema of the Lungs

1. Trauma.
   a. Injury to chest with or without fracture of the ribs.
   b. Operations on the chest, particularly the induction of pneumothorax.
2. Increase of intrapulmonary pressure.
   a. Straining with the glottis closed.
      Heavy lifting.
      Straining at stool.
      Childbirth.
      Attempts to resuscitate the newborn.
   b. Occlusion, partial or complete, of the trachea or bronchi; usually accompanied by cough.
      Anesthesia, especially closed method or inflation method.
      Asthma.
      Bronchitis.
      Foreign bodies.
      Whooping cough.
      Pneumonia.
3. Spontaneous rupture of alveoli.

When from any cause air accumulates in the retroperitoneal tissues, it may travel along the aorta or the esophagus and enter the mediastinum. Perforation of the stomach or the intestine may be followed by mediastinal emphysema.[2] The injection of air into the peritoneal cavity as a treatment for peritoneal tuberculosis [3] and the injection of air into the perirenal tissues to facilitate roentgenography of the kidneys has often produced mediastinal emphysema.

The entrance of air into the mediastinum through the fascial planes of the neck, directly from a rupture of the trachea, a main bronchus or the esophagus, or from the retroperitoneal tissues through the diaphragm, occurs only rarely and is of little practical importance compared with the usual path of entrance through the interstitial tissues of the lung. When alveoli lying on interstitial bands of connective tissue rupture, air enters the tissues about and travels along the course of the arteries to the mediastinum. It is possible that air may proceed in the opposite direction and lodge beneath the visceral pleura, but pressure gradients take most of the air, if not all of it, toward the hilus of the lung.

3. Banyai, A. L., and Jurgens, G. H.: Mediastinal Emphysema as a Complication of Artificial Pneumoperitoneum, J. Thoracic Surg. **8**: 329, 1938.

There are many circumstances that cause interstitial emphysema of the lungs. I cannot name them all but will group them in the accompanying tabulation.

Penetrating wounds of the chest that pierce the lung may rupture alveoli and produce interstitial emphysema and mediastinal emphysema. Injury to the chest with fracture of ribs is the common cause. However, it has been observed again and again that crushing injuries to the chest without an open wound or fracture of the ribs may be followed by mediastinal emphysema. In performing artificial pneumothorax the needle often enters the lung and, if air is allowed to flow in, the interstitial tissues may become infiltrated and air reach the mediastinum.[4] Slight degrees of mediastinal emphysema occur frequently but usually are overlooked.

Mediastinal emphysema may follow any form of exertion but particularly straining with the glottis closed. Cases are recorded that have come on after heavy lifting, after straining at stool and many during childbirth. Faust [5] in 1940 collected from medical literature 130 reported cases arising during labor, most of them in primiparas.

Occlusion of the trachea or bronchi is a fertile cause of rupture of pulmonary alveoli. If the bronchial occlusion is complete there is collapse of the portion of the lung supplied by the bronchus with overdistention of the surrounding part of the lung; if the bronchial occlusion is incomplete there is distention of the portion of the lung supplied by the bronchus; if there is partial obstruction to the trachea both lungs become greatly distended. The overdistended alveoli may rupture. No doubt bronchial obstruction plays an important role in the production of mediastinal emphysema when it is associated with the administration of anesthetics,[6] although the increased pressure in the bronchial tree induced by certain methods of anesthesia may play an accessory role or even alone be the cause. It has been noted that mediastinal emphysema occurs particularly often when the closed method and the inflation method of inducing anesthesia are used. No doubt bronchial obstruction also plays a part in producing alveolar distention in inflammatory diseases of the lungs, especially when accompanied by severe paroxysms of coughing, for the commonest cause of bronchial obstruction is plugs of tenacious inflammatory material. This association occurs particularly often in pertussis, asthma [7] and pneumonia,[8] conditions frequently causing mediastinal emphysema. Foreign bodies in the bronchi act in the same way.

Of particular interest is the occurrence of mediastinal emphysema when there is no evidence whatever of the presence of any condition leading to increased intra-alveolar pressure.[9] It may come on in a perfectly healthy person when he is standing quietly or sitting in a chair. It has the appearance as though normal alveoli may rupture under ordinary conditions of intrabronchial pressure. If we assume that there must be some alteration of the alveolar wall, it is impossible to ascertain

what it may be. The fact that spontaneous mediastinal emphysema tends to recur suggests that there may be an inherited defect of tissue quality. Macklin,[10] who has particularly emphasized the importance of bronchial obstruction in causing mediastinal emphysema, thinks that this mechanism may come into play even in cases seeming to arise spontaneously. It is possible that alveolar walls may be stretched and thinned by overdistention and yet rupture hours after the overdistention has occurred.

ESCAPE OF AIR FROM MEDIASTINUM

When air reaches the mediastinum and is confined there it will gradually be absorbed. Why in some instances it is confined within the mediastinum whereas in other instances it discovers an exit is not fully understood. One factor of importance is the amount of air that enters the mediastinum which determines the pressure it exerts. When sufficient pressure develops, air always escapes from the mediastinum. This occurs invariably in experiments on animals when the lungs are forcibly inflated. Nevertheless the pressure exerted by the air seems not to be the only factor concerned in its escape, since sometimes it escapes when there is little increase of pressure, whereas at other times it is retained within the mediastinum when there is evidence of great increase of pressure. Apparently the location of the air within the mediastinum is an importane factor, air escaping easily from certain locations but only with difficulty from others. It seems always to travel with greatest ease in the connective tissue surrounding blood vessels.

When air escapes from the mediastinum it may follow one of three paths: (1) into the subcutaneous and deep tissues of the neck, (2) through the diaphragm, about the aorta and the esophagus, to the retroperitoneal tissues and (3) into the pleural cavities.

The escape of air into the neck is readily detected and usually is convincing evidence of the presence of mediastinal emphysema. However, it does not invariably indicate that air has come from the mediastinum, for subcutaneous emphysema in the neck may occur when there is a wound of the chest communicating with the lung or when air enters the fascial planes from the buccal or nasal cavities. These possibilities must be excluded before we may consider it diagnostic of mediastinal emphysema. Air having escaped through the jugulum into the subcutaneous tissues of the neck, it may spread widely over the body, to the head, over the chest and abdomen, to the legs. Rarely the subcutaneous tissues are infiltrated with air from the top of the head to the soles of the feet. Occasionally air passes up the neck along the deep fascial planes and produces great swelling of the submucous tissues of the mouth and throat.

When air in the mediastinum pierces the diaphragm and spreads through the retroperitoneal tissues, its presence in these tissues may be difficult to recognize. Usually patients complain of pain in the abdomen, sometimes of pain on swallowing. The accident happens not infrequently during the induction of pneumothorax and at subsequent refills.

The association between mediastinal emphysema and pneumothorax is an intimate one, the two very often occurring together. We may sum up the present state of our knowledge concerning the relationship by saying that air from the mediastinum frequently enters the pleural cavity but that air from the pleural cavity never enters the mediastinum. The truth of this statement is supported by experiment and by clinical observation. It has an important bearing on our interpretation of certain clinical facts and makes clear the mechanism of what is commonly called tension pneumothorax.

Following injury to the chest there is often great shortness of breath and cyanosis. On examination pneumothorax is discovered and when the pressure in the pleural cavity is measured it is found to be very high. The usual assumption is that the lung has been ruptured and that a valvelike opening has formed which permits air to enter the pleural cavity but prevents it from escaping. This mechanism perhaps does occur, but certainly it is not the invariable one or even the usual one. In many such instances there is also subcutaneous emphysema in the neck demonstrating the presence of mediastinal emphysema. Therefore it is possible that the injury may not have caused rupture of the pleura but rupture of pulmonary alveoli with the formation of interstitial emphysema of the lung, then mediastinal emphysema, then pneumothorax through rupture of the mediastinal pleura. Sometimes pneumothorax occurs on the side opposite to the one that has been injured, so-called contralateral pneumothorax. Contralateral pneumothorax is very simply explained as secondary to mediastinal emphysema, whereas it is difficult to explain it by assuming the existence of any other pathway. Whenever subcutaneous emphysema in the neck and pneumothorax exist together, it is altogether probable that both are secondary to mediastinal emphysema.

The evidence of experiment demonstrates clearly that air may pass from the mediastinum to the pleura. When air is forcibly blown into the lung, pneumothorax always occurs if sufficient force is used. In animals when death comes suddenly during such an experiment, autopsy reveals bilateral pneumothorax with collapse of both lungs. The lungs then taken from the body may be inflated under water and no evidence found of a rupture or perforation of the visceral pleura.

THE EFFECTS OF AIR IN THE MEDIASTINUM

A small amount of air in the mediastinum may produce only trivial symptoms or none at all. Large amounts may cause very grave disturbance and in some instances lead to death. It has been commented on that when there is extensive subcutaneous emphysema the symptoms of increased mediastinal pressure are apt to be slight, whereas when there are grave symptoms of mediastinal pressure there is usually little subcutaneous emphysema. The entrance of air from the mediastinum into the pleural cavity does not offer such a safe escape for increased mediastinal pressure. The capacity of the pleural cavity will accommodate only a small amount of air before increased tension in the cavity adds to the symptoms of mediastinal pressure.

The effects of increased mediastinal pressure are similar to those of increased intrapericardial pressure. As the pressure rises the veins collapse, the inflow of blood into the heart is hindered, and if the pressure rises sufficiently high the circulation of the blood comes to a standstill. As the circulation becomes impeded, dyspnea and cyanosis come on and a little later pulmonary edema develops to aggravate these symptoms. If the pressure rises further the symptoms become more and more severe and finally end in death. Macklin has

10. Macklin, Charles C., and Macklin, Madge T.: Pulmonic Interstitial Emphysema and Its Sequelae: An Anatomical Interpretation, in Essays in Biology in Honor of Herbert M. Evans, Berkeley, Calif., University of California Press, 1943; Critical Review of the Literature with Extensive References, Medicine, to be published.

suggested that when mediastinal emphysema follows rupture of pulmonary alveoli the interstitial emphysema may press on the blood vessels and by interfering with the circulation in the lung promote dyspnea and cyanosis. Clinical observation demonstrates clearly that as the circulation fails pulmonary edema comes on, further to increase the respiratory embarrassment.

There are many experimental observations that demonstrate the course of these events. For instance, Jehn and Nissen [11] injected air directly into the mediastinum of rabbits and dogs. As long as the pressure in the mediastinum remained at ± 0 no recognizable symptoms developed, although breathing at times became more rapid and the blood pressure a little higher. As more air was introduced the blood pressure fell and the respiratory variations disappeared. Then came a period of apnea, followed by intense dyspnea and cyanosis; the veins in the neck stood out prominently, the eyes protruded and air appeared in the subcutaneous tissues about the jugulum. If the injection of air was stopped at this point some of the animals recovered, but in most there was an abrupt fall of blood pressure soon followed by death.

At the postmortem examination there was found extensive subcutaneous emphysema over the front of the chest, the air bubbles arranged in rows, resembling strings of pearls. When the mediastinum was opened the heart and large blood vessels were surrounded by air bubbles. The auricles, the upper and lower vena cava and the extrapulmonary portion of the large pulmonary veins were collapsed. Air was found along the esophagus and aorta, penetrating the diaphragm and collecting in the perirenal tissues. All of the organs showed a high degree of passive congestion.

At operation on man conditions have been found resembling those seen in animals with increased mediastinal pressure. For instance, Sauerbruch reports operating on a man after an automobile accident. "The collapsed lung was found lying against the mediastinum, which was blown up like a cushion. The vena cava was as large as a child's arm, the azygos vein as large as a man's thumb. Upon incision of the mediastinal tissue the air escaped and the mediastinum assumed its normal proportions."

THE CLINICAL MANIFESTATIONS OF MEDIASTINAL EMPHYSEMA

The symptoms of mediastinal emphysema are (1) pain, (2) subcutaneous and retroperitoneal emphysema, (3) obliteration of cardiac dulness, (4) peculiar sounds heard over the heart, (5) evidence of increased mediastinal pressure, dyspnea, cyanosis, engorged veins, circulatory failure, (6) pneumothorax and (7) roentgenographic evidence of air in the mediastinum.

When only a small amount of air gets into the mediastinal tissues no symptoms may be produced. The appearance of air in the subcutaneous tissues of the neck may be the first indication that mediastinal emphysema has occurred. No doubt slight degrees of mediastinal emphysema often are overlooked. Pain, sometimes mild, sometimes severe, may be the only symptom. Evidence of increased mediastinal pressure, dyspnea, cyanosis and embarrassment of the circulation occurs relatively seldom. I shall speak of each symptom separately, then group them together as they naturally occur to produce the typical clinical pictures of mediastinal emphysema.

The distention of mediastinal tissues with air nearly always causes pain. This is particularly conspicuous when mediastinal emphysema occurs in otherwise healthy persons, as it does, for instance, in spontaneous interstitial emphysema of the lungs. Indeed, there is clinical evidence that persuades me to believe that dissection by air of the interstitial tissues of the lungs may cause pain even before air reaches the mediastinum. Often patients complain of pain in the side for hours before the more severe pain and oppression of mediastinal emphysema come on. The pain is usually situated beneath the sternum and radiates over the chest, to the shoulders and sometimes down the arms, in which case it is quite like the pain of angina pectoris. In addition to sharp pain there is usually a feeling of oppression or constriction under the sternum, often with a little shortness of breath. Sometimes patients complain of pain on swallowing or on turning the head. When mediastinal emphysema follows operation or trauma to the chest, the pain caused by distention of the mediastinal tissues may not be clearly defined, since the patient's sensorium may be dulled or else the pain of mediastinal emphysema may be mingled with the pain of the operation or the trauma.

It seems to me that distention of the mediastinal tissues is a satisfactory explanation for the pain. The fact that the lungs and mediastinal tissues are not directly supplied with filaments from the spinal nerves is no valid objection to this view. In almost every part of the body distention and dissection of tissues cause severe pain even in locations not supplied with branches of the spinal nerves. The interesting suggestion has been made that the pain may be due, at least in part, to interference with the coronary circulation due to pressure on the heart by the distended mediastinal tissues. Whether or not this mechanism is really concerned I cannot say, but I think it unnecessary to invoke the mechanism to explain the pain since it is satisfactorily explained by ascribing its cause to the distention and dissection of mediastinal tissues.

If subcutaneous emphysema appears in the neck under circumstances in which there is no other cause for it, then we are assured that mediastinal emphysema is present. It is conclusive evidence of the existence of mediastinal emphysema and sometimes the only evidence. Why subcutaneous emphysema should occur in 1 case and not in another when in other respects the 2 cases are alike is not clearly understood. It seems that this difference must depend on the fascial planes along which the air chances to travel, some planes connecting freely with the subcutaneous fascia, other planes not connecting freely, and still other planes having no connection with them. It may be that when air has free access to the subcutaneous tissues increased pressure in the mediastinum is avoided, whereas when air is trapped in the mediastinum, symptoms of increased pressure are apt to arise.

If the mediastinal tissues that cover the heart become infiltrated with air, characteristic symptoms occur which are of great importance for diagnosis. The symptoms are two: obliteration of cardiac dulness and peculiar sounds heard over the heart. When only a small amount of air reaches the mediastinum cardiac dulness may not be obliterated and I have no doubt that at times the distinctive auscultatory signs may be absent, although in their absence it would be difficult to decide with certainty that mediastinal emphysema is present. I have not seen an instance of mediastinal emphysema clearly established by the evidence of subcutaneous emphysema

11. Jehn, W., and Nissen, R.: Pathology and Symptoms of Mediastinal Emphysema, Deutsche Ztschr. f. Chir. **206**: 221, 1927.

in the neck or characteristic roentgenograms in which the peculiar sounds over the heart were not heard.

These peculiar sounds consist of crackles, bubbles or churning sounds heard with each contraction of the heart. They may be heard only during systole or during systole and diastole, but always with systolic accentuation. They may be so soft that to be heard they must be listened for attentively; they may be so loud that they can be heard at a distance. Very often the patient himself is aware of the sounds and calls attention to them. They may be loudest over the lower portion of the sternum and to the left of the sternum or near the apex of the heart. They may be heard when the patient sits up and disappear when he lies down or be plainly heard when he lies on the left side and absent in other positions. When the presence of mediastinal emphysema is suspected the heart should be listened to carefully as the patient shifts from one position to another. The sounds are so characteristic that once having been heard thereafter their significance is unmistakable. They have been misinterpreted as the signs of pericarditis or pneumopericardium. I have the firm impression that some of the cases reported as instances of pneumopericardium were, in fact, instances of mediastinal emphysema.

Now that we are becoming aware of the fact that mild forms of mediastinal emphysema occur very frequently, we learn that increased mediastinal pressure is an unusual complication. Nevertheless, when it does occur it is a grave matter and it is especially important to recognize its presence since appropriate treatment may be life saving. I have already spoken of the observations made at experiments on animals and also by surgeons at operations on human beings after crushing injuries to the chest. With increasing rise of mediastinal pressure there is increasing obstruction to blood reaching the heart. The peripheral veins become distended and there are cyanosis and dyspnea. As the pressure in the mediastinum continues to mount, cyanosis and dyspnea become extreme and finally there is collapse with the signs of complete circulatory failure. There can be no slightest difficulty in appreciating the gravity of these symptoms; the important matter is to be aware of the mechanism that is causing them and to be prepared to deal with the situation effectively.

I have already commented on the fact that there is an intimate relation between mediastinal emphysema and pneumothorax. Very often they occur together. The important clinical point in this relationship is that when pneumothorax exists the presence of mediastinal emphysema may be overlooked. Perhaps if carefully searched for it will more often be found. It is a matter worthy of note that with spontaneous mediastinal emphysema there is an associated pneumothorax in about one third of the cases. The fact that the pneumothorax is usually very small and discovered only in roentgenograms makes it all the more important as evidence that the air in the pleural cavity had come by way of the mediastinum. The only other mechanism that might be suggested as a plausible explanation for the pneumothorax is to assume that air in the interstitial tissues of the lung had found its way not only to the mediastinum but also to the subpleural tissues and there had formed a pleural bleb which had ruptured. What evidence we have indicates that the first named mechanism is the usual one and that the second occurs rarely if ever. Therefore it is reasonable to surmise that cases of spontaneous pneumothorax may follow interstitial emphysema of the lungs and mediastinal emphysema,[12] even though the presence of mediastinal emphysema might elude clinical detection.

It is in considering the mechanism of tension pneumothorax that mediastinal emphysema comes prominently to the fore. The view generally held is that tension pneumothorax is due to a rupture through the pleura with a valvelike structure that allows air to enter the pleural cavity but prevents its escape. Since at autopsy it would be difficult to demonstrate the existence of such a valvelike structure, it seems to me that it requires a degree of credulity to accept this supposition. On the other hand, I find it much easier to accept the supposition that the pneumothorax is secondary to mediastinal emphysema. Were this actually the mechanism, it would not be necessary to assume the presence of a complicated valvular structure. There are certain clinical observations which convince one that at least sometimes pneumothorax is secondary to mediastinal emphysema. For instance, when following a blow to the chest, without fracture of the ribs or an open wound, pneumothorax occurs and at the same time subcutaneous emphysema in the neck, there can be little doubt that the sequence of events has been rupture of alveoli, interstitial emphysema of the lung, mediastinal emphysema, escape of air into the subcutaneous tissues of the neck and perforation of the mediastinal pleura with the production of pneumothorax. When the pneumothorax is contralateral this conclusion is well nigh inescapable.[13]

Careful fluoroscopic and roentgenographic examination is a valuable aid to diagnosis. In many instances collections of air are plainly seen, but often the evidence for the presence of air must carefully be sought. In the lateral view streaks of air sometimes may be seen in the mediastinal tissues between the heart and the chest wall. In the anteroposterior view a sharply defined translucent band outlining the course of the pericardium, especially along the upper part of the left border, is distinctive.

DIAGNOSIS

The diagnosis of mediastinal emphysema is easily made if the observer is familiar with the clinical manifestations. Many very mild cases occur with such slight and transient symptoms that the diagnosis may only be suspected but cannot definitely be confirmed. Pain, without fever, leukocytosis or other symptoms of a constitutional reaction, with obliteration of cardiac dulness and the presence of characteristic bubbling, crackling sounds with each contraction of the heart is a distinctive clinical picture. If, in addition, subcutaneous emphysema appears in the neck, the diagnosis is firmly established. The practical importance of these mild cases is that the diagnosis be correctly made. Often they are mistakenly diagnosed as coronary occlusion and pericarditis. Many cases have now been reported in medical literature and from these we are familiar with the varying details of the clinical picture. As an illustration I will cite briefly the following additional case:

A man aged 26 consulted my associate, Dr. Charles W. Wainwright, on Jan. 6, 1944 complaining of pain in the chest. On Christmas eve, while trimming a Christmas tree, he had been seized suddenly with severe pain in the left shoulder radiating to the upper part of the sternum, which forced him

12. Hamman, L.: A Note on the Mechanism of Spontaneous Pneumothorax, Ann. Int. Med. 13: 923, 1939.
13. Stephens, H. B.: A Consideration of Contralateral Pneumothorax as a Complication of Intrathoracic Operations, J. Thoracic Surg. 5: 471, 1936.

to bed, where he sat propped up on pillows, bending forward. This position had given him some comfort, whereas an attempt to lie down had made the pain worse. The intensity of the pain had soon abated, but soreness and discomfort had persisted for a week and at the time of his visit he still complained of pain when he took a deep breath.

He was a sparsely nourished man of healthy appearance. The general physical examination was entirely negative. An anteroposterior roentgenogram of the chest revealed no abnormality. Studies of the blood and of the urine gave normal results. The electrocardiogram was reported "Rate 83, sinoauricular rhythm, PR interval 0.16, QRS duration 0.08, T_1, T_2 and T_3 inverted. Normal axis. The concordant inversion of the T waves might suggest pericarditis."

What gave particular interest to this incident was the patient's history. At 15 years of age while at a summer camp he had had a sudden severe attack of pain in the shoulder, which had radiated over the upper part of the chest. Some pain and soreness had persisted for a month. At 19 years of age he had had a precisely similar attack. In July 1941, as a sequel to a mild sore throat, he had again been taken suddenly with a severe pain in the left shoulder, which had radiated to the sternum and had been greatly intensified by deep breathing. The following day he had entered the hospital and at the end of an examination the physician had told him that there was a definite pericardial friction and that he undoubtedly had pericarditis.

At about 1:30 on the morning of Jan. 20, 1944 the patient was taken with epigastric discomfort and distention. Thinking that these symptoms were due to indigestion, he induced vomiting. During the violent retching that followed suddenly he was seized by severe pain in the chest, which radiated upward to the shoulders. He described the sensation by saying it felt as though the chest was being forced apart by some expanding force. After the intense pain had passed there continued pain in the shoulders made worse by deep breathing and coughing.

Later in the morning he was admitted to the Johns Hopkins Hospital. Examination at that time again was quite negative. The heart and lungs appeared to be normal. However, the following day loud coarse bubbling sounds were heard with each contraction of the heart, at first only near the apex and only in certain bodily postures, later more generally over the body of the heart. At the same time subcutaneous crepitus was felt near the left sternoclavicular joint. A roentgenogram of the chest showed the heart and great vessels outlined by a thin radiolucent band, an appearance characteristic of air in the mediastinum. The electrocardiogram was identical with the one taken nine days before except that T_1, previously inverted, had now become upright.

On the third hospital day the peculiar sounds over the heart had disappeared and the patient was comfortable.

That the attack of pain on January 20 was due to mediastinal emphysema is clearly established. Therefore it is only reasonable to assume that the four preceding attacks of pain had all been due to the same cause.

Mediastinal emphysema occurring during the course of a severe febrile illness easily may be overlooked. It is a frequent complication of the specific infections of childhood, particularly of those with pulmonary disorders, measles, diphtheria and pertussis. During the influenza epidemic of 1917 and 1918 it was often observed, and in reports of the epidemic from military camps are excellent accounts of the clinical manifestations and of the mechanism of development.[8] In patients already prostrated and deeply intoxicated the added dyspnea and cyanosis of mediastinal emphysema may be misinterpreted. Heretofore the advent of subcutaneous emphysema in the neck is the symptom that has called attention to the presence of mediastinal emphysema.

After operation or trauma to the chest, dyspnea and cyanosis should always arouse the suspicion that mediastinal emphysema may be present. As a rule these symptoms are ascribed to a pulmonary complication, to faulty anesthesia or to the shock of the operation or trauma. I have seen instances in which the diagnosis of myocardial infarction has been proposed. Mediastinal emphysema is considered only when air appears in the subcutaneous tissues of the neck. I have already emphasized the fact that tension pneumothorax is usually, perhaps always, the result of mediastinal emphysema. It is reasonable to anticipate that a growing awareness of the importance of mediastinal emphysema with careful examination and thoughtful consideration will lead to the correct diagnosis in an increasing number of cases.

TREATMENT

A small amount of air in the mediastinum is an innocent matter. The air is soon absorbed and no harm results. In this respect it is much like spontaneous pneumothorax. The only importance of its recognition is that the diagnosis of some serious disorder is avoided. On the other hand, when the pressure in the mediastinum rises the condition becomes threatening and grave consequences may follow. Under these circumstances it becomes imperative to furnish an exit for the trapped air. This problem has been approached in a number of ways.

Many surgeons have accomplished the desired result merely by making a deep incision into the tissues of the mediastinum through the jugulum. At times suction has been applied to facilitate the escape of air or a catheter introduced with or without suction. Others have attached a specially curved, large bore needle to a syringe and with this instrument have explored the mediastinum. They describe that on occasions air has rushed out so forcibly that the plunger of the syringe has been ejected. Rarely these simple methods have not sufficed. Wustmann [14] made an incision through the jugulum, but even with suction no air could be aspirated because the aperture of the mediastinum was obstructed by a substernal goiter. The goiter was removed but still the obstruction persisted, apparently because of the thymus gland and large masses of thymus fat. Then the sternum was split and prompt relief followed.

Appropriate treatment for tension pneumothorax has long been established. It consists in frequent aspiration of the pleural cavity or, better still, the constant maintenance of atmospheric pressure. This may be done by using the apparatus for inducing pneumothorax or more simply by introducing a needle attached to a piece of rubber tubing the other end of which is inserted into a bottle of water. When there is clear evidence of associated mediastinal emphysema it might be an added advantage simultaneously to provide a way for the escape of air from the mediastinum. Gaudrault and Chalmers [15] in 1 case of mediastinal emphysema, occurring as a sequence to interstitial emphysema of the lungs, incised the mediastinal tissues through the jugulum and then induced pneumothorax to collapse the injured lung, hoping in this way to prevent the further escape of air from ruptured alveoli.

SULFADIAZINE IN TREATMENT OF RELAPSING MALARIAL INFECTIONS DUE TO PLASMODIUM VIVAX

L. T. COGGESHALL, M.D.
Chairman, Department of Tropical Diseases, University of Michigan School of Public Health
ANN ARBOR, MICH.

COLONEL WALTER B. MARTIN
MEDICAL CORPS, ARMY OF THE UNITED STATES
AND
CAPTAIN ROBLEY D. BATES JR.
MEDICAL CORPS, ARMY OF THE UNITED STATES

Interest in malaria has been stimulated in the United States by the high incidence of relapsing malaria in troops returning from service in endemic malaria areas. It has been observed in all hospitals receiving these patients that the relapse rate is high, particularly in Plasmodium vivax malaria. The recognized failure of quinine, atabrine and plasmochin in various dosages, singly and in combinations, to affect the relapse rate materially is a matter of concern and serves to emphasize the importance of developing new methods of treatment. For this reason and because the amount of available quinine has been considerably reduced, a search for more satisfactory compounds continues.

In monkeys the virulent Plasmodium knowlesi strain of malaria is highly susceptible to sulfanilamide.[1]

TABLE 1.—*Recurrences*

Percentage of recurrences	46.2

Reports concerning the effectiveness of related drugs on human strains have appeared in the literature during the past few years.[2] While these reports have been somewhat conflicting, the evidence thus far indicates that both quinine and atabrine are more efficient than any other drug so far tested in the treatment of naturally acquired P. vivax infection. The suggestion that sulfonamide compounds might be capable of eradicating an infection which was already clinically suppressed by a previous course of one of the other drugs resulted in the trial of such a program in treatment of a group of patients whose infection originated in the Southwest Pacific area. Furthermore, since it has been shown[3] that there are striking clinical differences between strains and between artificial (induced) and natural (acquired) malaria, it seemed worth while to investigate the effect of sulfadiazine on the particular strain contracted in the Southwest Pacific area.

The present report concerns a series of 33 relapsing infections treated in this fashion at the Percy Jones General Hospital. In each instance the diagnosis was established by demonstrating the parasite in the stained blood smear. Plasmodium vivax was found in every case. In 1 instance (D-10) Plasmodium falciparum gametocytes were also encountered. The patients were not selected but were taken in consecutive order as clinical relapses occurred during a six weeks period in the summer of 1943.

DETAILS OF TREATMENT

In all but 3 cases the acute clinical symptoms were controlled by administering 0.1 Gm. of atabrine three times a day for seven days. On the eighth day administration of sulfadiazine was begun according to the following schedule: On the first day 8 Gm. was administered, and then 1 Gm. was given every four hours night and day for one week. This schedule was modified only when the blood level of the drug went above 15 mg. per hundred cubic centimeters. This occurred in only 1 case. At the beginning of the second week the dosage was dropped to 1 Gm. every six hours day and night regardless of blood concentration, provided it did not go too high. Three patients, as indicated in table 2, were given quinine instead of atabrine over either a five or a seven day period, but otherwise standard conditions were maintained throughout. Blood sulfadiazine levels were obtained at the end of the first twenty-four hour period and at three day intervals thereafter. An attempt was made to maintain a blood level of 8 to 10 mg. per hundred cubic centimeters the first week. In the second week we were interested in the effect on the plasmodium of long continued exposure to the drug. The usual laboratory studies were made at the same time. These included leukocyte count, differential smear, hemoglobin and urinalysis. There were no toxic manifestations other than mild microscopic hematuria in 3 patients. This

did not require discontinuance of the drug but cleared spontaneously after increase in fluids and alkalization of the urine.

RESULTS

Table 1 shows a relapse rate of 46.2 per cent in 134 patients treated at this hospital from Feb. 15, 1943 to Sept. 15, 1943. As can be seen, these figures were obtained from the number of relapses following all types of treatment employed by us except sulfadiazine therapy. This group was excluded for purpose of comparison. A number of different forms of therapy were employed, consisting of various dosages and combinations of quinine, atabrine and plasmochin. On the basis of their effect on the relapse rate all of these methods of treatment were equally ineffectual. The use of plasmochin was discontinued on August 17, with the exception that it was given to a few persons with P. falciparum malaria. We have not observed any change in frequency of relapses since discontinuing its use.

Table 2 summarizes the pertinent data relative to the sulfadiazine series, such as blood level of sulfadiazine, type of malaria and intervals between treatment and recurrences up to Nov. 1, 1943.

Although it has been only three months since the last member of this group finished treatment, it is felt that sufficient time has elapsed to demonstrate the ineffectiveness of sulfadiazine in preventing recurrences of P. vivax malaria, since 16 of 33 patients, or 48.5 per cent, have already relapsed.

COMMENT

As shown by the charts, the incidence of relapse in the sulfadiazine treated group is almost exactly the same as in the group treated by various combinations of quinine, atabrine and plasmochin, despite the fact that in each instance in the sulfadiazine series the acute attack was controlled by atabrine or quinine. Conditions were standard for all patients, and satisfactory blood levels were maintained. The average of concentration per patient ranged from 4.7 to 10.7 mg. per hundred cubic centimeters. In the 16 cases that relapsed after sulfadiazine therapy the average blood concentration was 7.7 mg. per hundred cubic centimeters, while in 17 who have not yet relapsed it was 7.6 mg. In the relapsing cases the average peak concentration was 10.6 mg. per hundred cubic centimeters and the peak range from 7.7 to 15 mg., while in the nonrelapsing cases the average peak concentration was 10.2 mg. and the range from 6.4 to 12.7 mg. per hundred cubic centimeters. It is evident that there was no essential difference in blood concentration obtained in the two groups and that this therapy has no value in preventing relapses of P. vivax malaria. It is realized that there is considerable variation in susceptibility to treatment among strains of the same species, and this may be an important factor in the poor results obtained in this series. It is known that when a foreign strain is introduced into nonimmune persons the character of the infection tends to be more severe. Therapeutic malaria has been generally recognized as being far more susceptible to quinine, and the tendency to recurrences is much less. This relates particularly to any artificially induced malaria, where the relapse rate is practically nil. Most antimalarial drugs give satisfactory results in such patients. It is possible, therefore, that sulfadiazine may be useful in the treatment of therapeutic malaria, whereas it appears to be of no value in preventing relapses in naturally acquired Plasmodium vivax of the type encountered in soldiers returning from the South Pacific.

It is significant that only 1 patient in this group had his initial attack of clinical malaria in this hospital. It is generally accepted that each relapse reduces the chance of another one. The group receiving sulfadiazine showed no appreciable variation in the number of previous attacks from those treated with atabrine or quinine alone. As a matter of record, the average number of previous attacks for the group relapsing after sulfadiazine was 2.5 and for the nonrelapsing group it was 2.7. Consequently one can dismiss such a factor in the comparison of the recurrence rate between the two groups.

It seems worth while to discuss the problem of these persistent P. vivax malarial infections acquired in the South Pacific. There is considerable speculation at the present time as to whether they are more virulent and whether they have a greater tendency to have renewed clinical activity than strains of the same species reported elsewhere. In field studies there is always present the difficulty of differentiating relapses from reinfections. The most conclusive results come from the observations in therapeutic malaria, where the possibility of reinfections has been eliminated. Boyd's [4] investigations have shown that 68, or 45.6 per cent, of 149 patients whose infections were initiated by infected mosquitoes with the McCoy strain of P. vivax malaria had renewed clinical activity after termination of the initial attack. In this respect these experiences are comparable to those encountered at the Percy Jones General Hospital. However, there is one striking difference; whereas in Boyd's 146 patients 68 had only one recrudescence,[5] 23 had two, 8 had three, 4 had four, 2 had five and only 1 had six. The tendency for more recrudescences in the South Pacific infections was much greater, as over 50 per cent of the patients had more than three recrudescences and a few as many as twelve. It might be stated that this again could be attributed to the fact that this was a selected group, but most of the cases were not returned because of recurrent malaria but because of other disablements. Hence it seems from comparisons of the available data for these patients and Boyd's studies that the South Pacific P. vivax malaria has a greater tendency for persistent infections. The subject will be covered in greater detail in later studies from the same institution in connection with the complement fixation reaction and diagnosis of malaria.

SUMMARY AND CONCLUSIONS

Thirty-three patients with vivax malaria acquired in the Southwest Pacific area were treated with sulfadiazine over a two week period. Acute clinical symptoms were controlled by a course of atabrine or quinine immediately preceding sulfadiazine therapy. Sulfadiazine blood levels of 4.7 to 10.7 mg. per hundred cubic centimeters were obtained in each instance. Follow-up on these patients three months later revealed that 16 had relapses, an incidence of 48.5 per cent, whereas our relapse rate for patients treated by usual courses of atabrine or quinine was 46.7 per cent.

Sulfadiazine is of no value in preventing relapses in the strain of P. vivax malaria naturally acquired in the Southwest Pacific area and deserves no place in the therapy of this type of malaria.

4. Boyd, M. F., and Kitchen, S. F.: Recurring Clinical Activity in Infections with McCoy Strain of Plasmodium Vivax Malaria, Am. J. Trop. Med. 17: 833, 1937.

5. The word "recrudescence" is preferred following S. P. James's suggestion (Some General Results of Induced Malaria in England, Tr. Roy. Soc. Trop. Med. & Hyg. 24: 477, 1931) that they are sequels to the initial attack occurring within eight weeks after the previous one. Most of the infections studied at the Percy Jones Hospital fell into that category. James designated a relapse as a renewed attack of clinical activity occurring after a quiescent period of eight weeks to six months.

COLON SURGERY AND THE SULFONAMIDE DRUGS

WITH ESPECIAL REFERENCE TO THE ELIMINATION OF THE MIKULICZ OPERATION

MOSES BEHREND, M.D.
PHILADELPHIA

Results of colon surgery at the turn of this century, as compared with the results of the present day, are marked by great improvement in recent years. This improvement has been due to many factors. The most important of all has been the careful preoperative preparation of the patients. Formerly, patients were admitted to the hospital and in a day or two were operated on. The bowels were full of feces and teeming with bacteria, and as a result the mortality after operation often ranged from 60 to 70 per cent, even in the hands of the best surgeons.

In the past ten or fifteen years, however, it became apparent that certain measures could be taken to reduce mortality. It was shown that one cause of the high morbidity and mortality was lack of preoperative preparation. It became an axiom in our service that operation should not be performed unless preceded by at least a week's preparation. This preparation, which consisted of a preliminary purge followed by colonic irrigations, a liquid diet and parenteral feeding, is well known. Blood transfusions before, during and after operations became a routine measure. The results obtained with this method showed an appreciable improvement. There was an immediate reduction in the mortality following operations on the colon after this regimen.

Then with the introduction of the sulfonamides, a new era in the surgery of the colon was inaugurated. Sulfanilamide was given by mouth, the primary dose being 120 grains (8 Gm.) in twenty-four hours, followed by a reduction in the dosage each day up to the time of operation. Before closing the abdomen 5 to 8 Gm. of sulfanilamide crystals was placed in the peritoneal cavity.

Like all innovations in medicine, the new bactericidal or bacteriostatic agents were not universally accepted. Even now there is some skepticism about the efficacy of these drugs, and rightly so, in certain conditions. I was one of those to whom the magical effects of the drug had to be demonstrated. But it was not long before the benefits were practically illustrated, especially in streptococcic infections.

SUCCINYLSULFATHIAZOLE

In January 1939 we first used the sulfonamides in colon surgery. In 1941 Poth and Knotts [1] introduced the use of succinylsulfathiazole, which has enabled us to change our technic in colon surgery, just as the use of vitamin K has given us an added security against postoperative hemorrhages in the jaundiced patient.

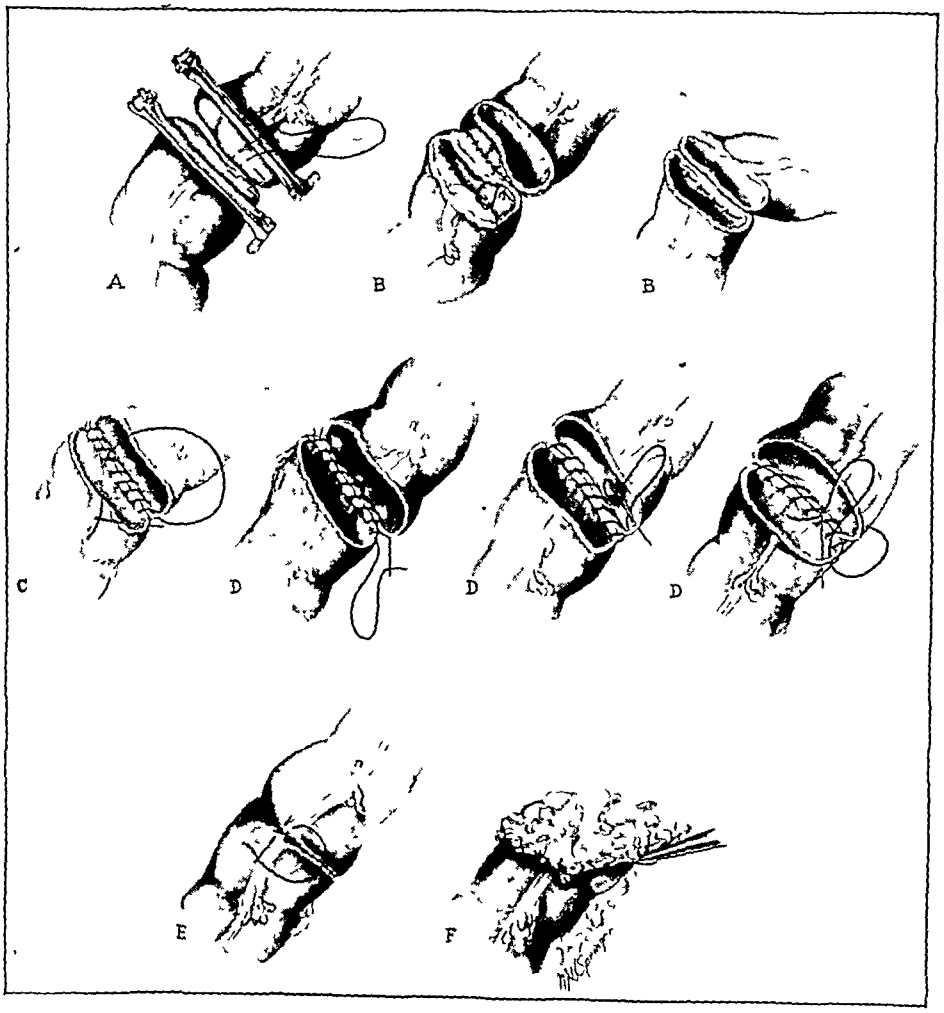

Fig 1.—*A*, first suture of linen thread on adjacent sides of the mesentery of the colon, *B*, interrupted mattress suture on an atraumatic needle with catgut, the knots of which are tied within the bowel, *C*, the adjacent free ends of the colon are sewed with a similar needle, threaded with 00 chromic gut, *D* (1, 2 and 3), the distal edges of the colon are brought together with a continuous Connell suture, *E*, interrupted or continuous Czerny Lambert sutures appose the serous surface; *F*, any available piece of fat is attached over the line of suture

Sulfonamides introduced intraperitoneally before the abdomen is closed are of benefit, and this policy has given our best results.

My associates and I experimented with most of the sulfonamide drugs as they were introduced, from sulfanilamide to sulfanilylguanidine, but we feel that succinylsulfathiazole is a product of real merit in rendering the coliform bacilli inert. This gives it an additional

From the services of the Jewish and Mount Sinai hospitals.

1. Poth, E. J., and Knotts, F. L.: Succinylsulfathiazole: A New Bacteriostatic Agent Locally Active in Gastrointestinal Tract, Proc. Soc. Exper. Biol. & Med. **48**: 129-130 (Oct.) 1941. Poth, E. J.: Succinyl sulfathiazole: Adjuvant in Surgery of the Large Bowel, J. A. M. A. **120**: 265-269 (Sept. 26) 1942.

advantage in the preparation of the patient. There is no necessity of estimating the blood concentration, because succinylsulfathiazole has no toxic effects. It simplifies considerably the preparation of the patients who are about to be operated on for cancer or any other lesion of the colon. The drug should be given in doses of 0.25 Gm. per kilogram of body weight for at least a week before the contemplated operation. It has been shown that it is not necessary, with the administration of this drug, to give colonic irrigations, because the drug has the property of diminishing the contents of the intestinal tract, rendering it practically empty. It is amazing to compare patients who have been prepared without succinylsulfathiazole with those who have had the preoperative preparation with this drug. It makes the use of the various aseptic procedures in anastomosis of colon to colon unnecessary. Furthermore, instead of giving the patient a rigid liquid diet as formerly, a low residue diet may be ingested with impunity. In a recent paper, in a report of cases, I [2] stated that a liquid diet was strictly enforced. In several cases in which operation was recently performed, a low residue diet and liquids were allowed. The colon, as usual, was empty and odorless. In some cases, however, we may be compelled to adhere only to a liquid diet.

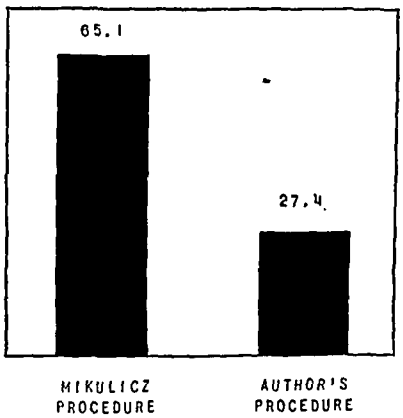

Fig. 2.—Average number of days in the hospital.

EFFECTS OF SUCCINYLSULFATHIAZOLE AND THE ONE STAGE OPERATION

Now, with the added assurance that the bacterial flora will be reduced to a minimum by the use of succinylsulfathiazole, a one stage operation, whenever feasible, has been performed. It is well known that the many stage operation, exemplified by the Mikulicz procedure, is probably the safest type of operation that one can perform on the colon. If one can avoid the multiple procedure operation and if one has had enough experience in performing the one stage operation, I believe that in time it will induce all surgeons to use this technic. It subjects the patient to less surgery, the operation is cleaner, the convalescence is much shorter and the cost to the hospital and patient is greatly reduced. For example:

E. D., a Negro woman aged 50, admitted to the Mount Sinai Hospital in the service of Dr. Abraham Trasoff on March 3, 1944, was in good health until a month before, when she began to have generalized abdominal pain. She noticed also that the abdomen began to swell. She had loss of appetite with increasing constipation and lost a few pounds in weight. She had high blood pressure for the past seventeen years and suffered a stroke in September 1942, with hemiplegia of the left side. The blood pressure was 220/140, hemoglobin 48, red blood cell count 7,800,000. She had a carcinoma of the transverse colon close to the hepatic flexure. The tumor was widely excised, and an end to end anastomosis was performed. Exactly two weeks after the operation she was discharged from the hospital, whereas after the old type operation, with its many inconveniences, she would have been in the hospital from eight to twelve weeks.

The pathologic diagnosis was primary, obstructing, annular, ulcerating adenocarcinoma infiltrating all the coats of the colon, the lymphatic channels and the serosal layer.

There was no semblance of infection. No drainage was used, but it is now thought preferable to use a Penrose drain without gauze down to the point of anastomosis. In the past twenty-five years this has been the only patient of the colored race operated on in a large series of cancer of the colon. She was hypertensive and was characteristically afraid of an operation. She died suddenly, while doing her housework, three weeks after her operation.

TECHNIC OF OPERATION

After the lesion in the colon is reached, Stone or de Martel clamps are applied above and below the growth, and excision is performed with the aid of the cutting current of the Bovie apparatus. With the peritoneal cavity well walled off with gauze sponges, the first suture of linen thread is then begun on the adjacent sides of the mesentery of the colon (fig. 1 *A*). The clamps are now removed. The next suture is an interrupted mattress suture, on an atraumatic needle with catgut, the knots of which are tied within the bowel (*B*). The adjacent free ends of the colon are sewed with a similar needle threated with 00 chromic gut (*C*). These sutures are all made on the posterior portion of the colon. The distal edges of the colon are now brought together with a continuous Connell suture (*D*). Interrupted or continuous Czerny-Lembert sutures of linen appose the serous surfaces (*E*). Any available piece of fat is then attached over the line of suture (*F*). Before the abdomen is closed, a piece of rubber dam is placed at the site of the operation to take care of any leakage that might occur.

MIKULICZ OPERATION

While I admit that the Mikulicz operation may be necessary in some selected cases, its field of usefulness will eventually be eliminated. The reasons are as follows:

1. Though it is true that the number of stages has been shortened by combining the first and second stages with the removal of the growth, nevertheless at least two or three successive steps are required, and in some patients who do not heal kindly, additional procedures may be necessary to close the colostomy. One patient was in the hospital 101 days—others ranged from 52 to 96 days.

2. The number of days of bed occupancy is also a prime consideration. As stated, every patient operated on by the Mikulicz method requires at least from eight to twelve weeks of hospitalization. Even if the patients are discharged between operations, the same length of time in the hospital is still required. We have reviewed, especially with this point in view, all cases recorded for the past twenty-five years in which we have performed the one stage in comparison with the two stage operation. The average stay in the hospital of the patient on whom the Mikulicz operation has been performed is 65.1 days. In the one stage procedure the average duration of hospitalization is 27.4 days (fig. 2).

3. Again, the inconvenience from the time the first operation is performed to the closure is considerable on account of the feces covering the field of operation. Several dressings a day are required, with a consequent additional drain on the hospital resources.

2. Behrend, M.: Succinylsulfathiazole (Sulfasuxidine) and the Elimination of the Mikulicz Operation, S. Clin. North America 24: 238-247 (Feb.) 1944.

ONE STAGE VERSUS MULTIPLE STAGE OPERATIONS

When obstruction is not present, there is seldom any necessity for a two stage operation on the colon for cancer. It is obvious that when there is an obstruction a preliminary colostomy must be performed as a primary procedure.

In secondary abdominal operations, adhesions are always an encumbrance. This is not an issue in the performance of the various stages of the Mikulicz operation, but where we have used the two stage operation in carcinoma of the cecum and ascending colon the adhesions found at the second operation were sometimes almost insurmountable. A one stage ileocolostomy therefore is preferred to the Mikulicz procedure for patients with cancer of the cecum and ascending colon.

The same may be said for the multiple stages of the Lahey and Rankin operations for carcinoma of the rectum. The one stage Miles abdominoperineal operation is so superior that I have practically abandoned the former types of operations.

An operation in which the Mikulicz procedure was avoided is illustrated by the following case:

R. L., a frail, very anemic looking woman aged 67, was admitted to the Jewish Hospital on March 12, 1944 to the service of Dr. Nathan Blumberg. On April 7 the operation was performed. Before admission she complained of abdominal cramps for the past two years. Hemoglobin was 39, the red blood cell count 2,770,000. The blood pressure was 150/70. Many transfusions were given prior to the operation, which was performed on April 4 for carcinoma of the transverse colon. The tumor was easily isolated, a de Martel clamp was applied and the mass was removed. An end to end anastomosis was then performed.

This was a bad risk. The patient looked ten years older than her actual age. Her convalescence was without incident. Her bowels moved on the fifth day following an oil retention enema. She was out of bed on the tenth day and ready for discharge on the fourteenth day following operation. While the Mikulicz operation is also a safe procedure, I believe, in this particular instance, the operation now advocated served its purpose better than the many stage operation.

* Whenever succinylsulfathiazole is found in the same bracket above with sulfanilamide or sulfathiazole, the latter drugs, in 5 to 10 Gm. doses, are placed in the peritoneal cavity before the abdomen is closed. Spinal anesthesia was used.

MORTALITY AND MORBIDITY

In 1943 there was not recorded a death in twenty-four successive colon operations. These operations included all the types of procedure, depending on the location of the lesion. It must be stated here, however, that we did not begin the use of succinylsulfathiazole until August 1943. No case in this series was treated without some type of the sulfonamides such as sulfanilamide, sulfathiazole or sulfanilylguanidine. The outstanding difference with the use of succinylsulfathiazole is well expressed in Poth's statement that "the drug given in

therapeutic doses alters the feces, because they become semifluid and practically odorless. The coliform organisms are reduced to such low values that B. coli cannot be demonstrated by growth on desoxycholate plates." All multiple and one stage operations were performed under spinal anesthesia, with the results shown in the table.

On December 31 the twenty-fifth patient died from multiple emboli of the ulna and radial arteries causing gangrene of the fingers of the left hand:

B. J., a woman aged 70, admitted to the Jewish Hospital on Nov. 19, 1943, had been admitted four years before for carcinoma of the rectum with involvement of the posterior vaginal wall. A one stage abdominoperineal operation was performed at that time, with a resulting permanent colostomy. She made a good recovery and lived a normal life until her next admission in November 1943. At this time a mass was felt in the right iliac region, which also proved to be cancer. A one stage ileotransverse colostomy was performed. About three weeks before her death she developed cyanosis of the fingers of the left hand, followed by gangrene of these digits (fig. 3).

This case illustrates the fact that successive carcinomatous lesions in different parts of the colon in the same individual may occur after the primary lesion has been operated on. Four years before the first lesion was in the rectum; the second was in the cecum and ascending colon. She unfortunately was attacked by multiple emboli affecting the left hand and fingers, ending in dry gangrene. This was followed by cyanosis and signs of beginning gangrene of the right hand and fingers.

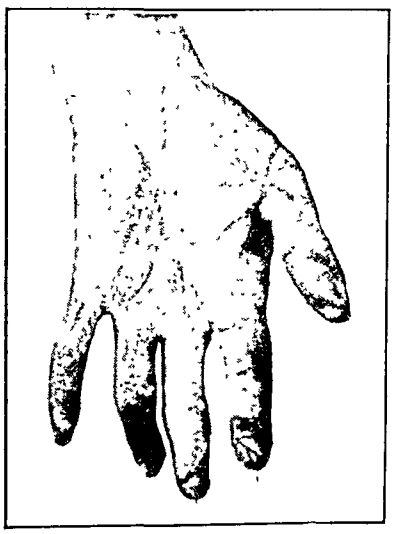

Fig. 3.—Gangrene of fingers following operation for carcinoma of the cecum and ascending colon.

The use of spinal anesthesia must be considered as another contributing factor in the reduction of the mortality of colon cases. When a prolonged operation is contemplated, continuous spinal anesthesia is employed; in other cases a single dose of 150 mg. of procaine is used. Since 1928, spinal anesthesia has been used for over 90 per cent of the patients operated on.

SUMMARY

As stated in the beginning of this paper, good colon surgery was done before the entrance of the sulfonamides. Better results were due to an insistence on the preparation of these patients at least a week before operation. With a primary purge and an absolute liquid diet, the contents of the bowels were greatly reduced. In addition, parenteral fluids and blood transfusions were given.

It remained, however, for the sulfonamides to reduce the number of cases of peritonitis and infections.

The ultimate, however, was reached when succinylsulfathiazole was introduced. Here was a drug that could be given in large doses without toxic effects. It reduced the number of coliform bacteria per gram of wet stool from 10,000,000 to 100 organisms. It enabled us to reduce the several stage Mikulicz operation to a single procedure.

STUDIES ON MERCURIAL DIURESIS

V. SUDDEN DEATH FOLLOWING INTRAVENOUS INJECTION

REPORT OF THREE CASES, WITH ELECTROCARDIOGRAPHIC STUDIES IN TWO

ITALO F. VOLINI, M.D.
CHICAGO
CAPTAIN ROBERT O. LEVITT
AND
MAJOR RICHARD MARTIN
MEDICAL CORPS, ARMY OF THE UNITED STATES

Mercury is a protoplasmic poison. It precipitates protein. The clinical use in the form of the nonionizable compounds in the organic mercurial diuretics has become very extensive in the therapy of edema and the symptoms resulting from accumulations of fluids. This diuretic action is just as powerful in the ionizable inorganic mercury compounds as in the organic ionizable combinations.

The diuretic action represents the very early toxic action of mercury on the renal tubules. The positive mercury ion released in small amounts from the organic mercurial diuretic accounts for the renal and diuretic effects. Sollmann, Schreiber and Cole have demonstrated that ionizable inorganic compounds of mercury are more potent in diuretic action than nonionizable organic mercurials. Mercury has been known for its diuretic activity since the time of Paracelsus and was a constituent of the Guy's Hospital pill, which contained calomel, squill and digitalis.

The earliest reports of sudden death were made by Redlick [1] in 1925 with three deaths from the use of novasurol. Intravenous salyrgan was indicated as the cause of death by Wolf and Bongiorno [2] in 1931. Sundaram [3] added one in 1934 and Greenwald [4] and Seymour reviewed two deaths in 1937. Another fatal episode was noted by Tyson [5] in 1941. Several extensive clinical reports appeared in 1941 and 1942, adding to the published fatalities, all appearing suddenly during or shortly after the intravenous injection of an organic mercurial diuretic administered to promote the removal of fluid from the body.

Experimentally in 1922 Salant and Kleitman [6] had observed ventricular fibrillation in dogs following intravenous administration of inorganic mercurial salts and mercurochrome. Jackson [7] in 1926 reported that he was able to produce death regularly by ventricular

fibrillation within three to five minutes in normal dogs under ether anesthesia by intravenous injection of various mercurial compounds.

Chastain and Mackie [8] in 1940 studied the effects of the sodium salt of pyridinedicarboxymercuri hydroxy propylamide theophylline (Esidrone), an organic mercurial diuretic combined with theophylline, when given intravenously to normal dogs under barbiturate anesthesia. By using five or six times the corresponding clinical dose they were regularly able to produce death by ventricular fibrillation. They found that twelve to fifteen seconds after the intravenous administration the electrocardiogram showed deviations of the ST interval and ST junction and the T waves followed by ventricular flutter and ventricular fibrillation. Death occurred in three to five minutes. We have published four investigations on Esidrone since 1938. This contribution represents the fifth report on the use of Esidrone. We observed Chastain and Mackie's report but found that their fatal results appeared consistently only after fifteen times the usual corresponding clinical dosage, so we did not attach to it the significance it probably deserved.

A symposium of several articles dealing with the toxicity of mercurial diuretics and reports of a considerable number of deaths appeared in THE JOURNAL on July 25, 1942. The contributions were made by DeGraff and Lehman,[9] Barker, Lindberg and Thomas,[10] Brown, Friedfeld, Kissin, Modell and Sussman [11] and DeGraff and Nadler.[12]

DeGraff and Lehman studied the relative toxicity of the various organic mercurial diuretics on the commercial market. Their work, carried out on cats, was very comprehensive and corroborated the evidence presented by Salant and Kleitman, Jackson, and Chastain and Mackie. DeGraff and Lehman showed that Esidrone was the most toxic of the mercurials, followed in order by salyrgan, mercurin, mercupurin with salyrgan theophylline, the least toxic. They demonstrated that the added theophylline radical played no important role in the production of sudden death and that previous treatment by various drugs such as ammonium chloride, phenobarbital, intravenous aminophylline and digitalis had no effect on the lethal dose of at least one of the mercurials. They also observed that dilution of the drugs is of little value in preventing sudden death. Nor were they able to prove that the rate or speed of the intravenous injection contributed to the toxicity and fatal termination. H. T. Hyman [13] believes that the reactions and sudden deaths are due to technical and not pharmacodynamic reactions. He maintains that the reaction resembles the syndrome of speed shock, anaphylactic or anaphylactoid responses, in which the blood is rendered noncoagulable. However, the evidence would seem to indicate that death is caused by the direct action of these drugs on the heart. Ventricular fibrillation or respiratory failure secondary to cardiac action is the usual manifestation and cause of death. Ventricular tachycardia frequently precedes the onset of ventricular fibrillation.

REPORT OF CASES

CASE 1.—W. S., a white youth aged 20 years, first examined May 2, 1940, gave a history of rheumatic fever and known heart disease for the previous nine years. The presenting complaints were dyspnea, orthopnea and cough, with edema of the lower extremities. The patient weighed 109 pounds (49 Kg.), the respiratory rate was 30 and he had an irregular pulse of auricular fibrillation with a rapid rate of 130 per minute. The blood pressure was 104/60. He was in definite congestive heart failure, with the left heart border extending to the left midaxillary line. The rapid irregular rate and presystolic, systolic and diastolic murmurs were audible over the precordial area. The liver extended almost a hand's breadth below the costal margin, with pronounced edema grade 4 of the lower extremities. The urine contained 4 plus albumin with a specific gravity of 1.026. The Kahn reaction was negative. The blood count showed normal findings. The chest film corroborated the pronounced enlargement of the heart, and the electrocardiogram demonstrated the auricular fibrillation. The diagnosis was rheumatic heart disease, with mitral stenosis and mitral regurgitation, aortic regurgitation, pronounced hypertrophy and dilatation of the right and left ventricles, the left auricle, auricular fibrillation and severe congestive heart failure.

Under rest, sedatives and digitalis 300 mg. the congestive failure disappeared and the ventricular rate was brought down to about 66, when a maintenance dosage of 200 mg. daily permitted the patient a fair degree of activity, although he could not go to work. He was seen at approximately three week intervals as an office patient until Sept. 4, 1941, about sixteen months after the first consultation, when a weight gain of 10 pounds (4.5 Kg.) was noticed. The digitalis was increased, but the next office visit showed an additional gain of 8 pounds (3.6 Kg.) on Oct. 6, 1941, when he was told to remain at home, where he was visited every few days. The response to digitalis 500 mg. daily was unsatisfactory. The signs of congestive failure became pronounced, with the symptoms severe, so 1 cc. of mercupurin was administered intravenously.

A diuretic response of 4,100 cc. resulted. Three days later a second dose of equal amount was used with 1,300 cc. output in twenty-four hours. The symptoms did not improve with a third injection of 1 cc. two days later, with only 1,000 cc. of urine. Two cc. of mercupurin from the same box was given two days later. The injection was made at a rate similar to the previous administrations, rather rapid in all instances. Very shortly after the withdrawal of the needle the patient complained of pain in the precordium, was very restless and became rapidly unconscious, with convulsive movement of the eyes and general twitching of the skeletal muscles. The pulse prior to injection was rapid and irregular, becoming very rapid as the symptoms of the episode appeared, finally became thready and disappeared. Death occurred within a few minutes after the injection. The clinical evidence supported the diagnosis of the onset of ventricular tachycardia followed by ventricular fibrillation.

CASE 2.—W. M., a white man aged 68, entered Cook County Hospital on April 14, 1938 complaining of shortness of breath, loss of appetite and swelling of the legs and abdomen of one year's duration. The past history was irrelevant.

The patient breathed with extreme difficulty. There was cyanosis of the finger nails. The blood pressure was 166/102. The cardiac apex was palpated at the left anterior axillary line in the sixth interspace. A loud systolic murmur was audible over the apex and at the aortic cartilage. The heart tones were distant and rapid; the rate was 130 per minute but regular. Rales of congestion were audible in the lungs. The liver was three finger breadths below the costal margin. Free fluid was present in the abdomen. Peripheral edema was massive. The laboratory evidence showed a negative Kahn reaction, red blood cells 4,530,000, white blood cells 7,300. Hemoglobin was 70 per cent and the differential count was 56 per cent lymphocytes and 44 per cent polymorphonuclears. The nonprotein nitrogen was 43 mg. per hundred cubic centimeters. Blood carbon dioxide was 48 volumes per cent. The urine showed a specific gravity of 1.020, albumin 2 plus, sugar negative. The x-ray film demonstrated cardiac enlargement,

some enlargement of the aortic arch and pulmonary congestion. The diagnosis was hypertensive and arteriosclerotic heart disease with pronounced enlargement of the heart and congestive heart failure, grade 4. The electrocardiogram taken three days after admission showed left axis deviation, auricular extrasystoles, ST junction depression in lead 4, the ST interval and

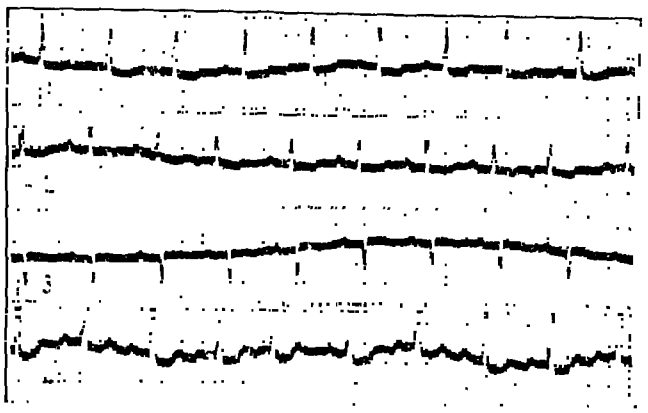

Fig. 1 (case 2).—Tracing of April 17, 1938.

T changes in leads 1, 2 and 4. Part of the latter evidence presumably could be from the heavy digitalis medication which was initiated shortly after admission and for three days prior to the electrocardiogram. Morphine and atropine were employed to quiet the patient. On April 18, 1938, 1 cc. of Esidrone was administered with a 5,900 cc. urinary output resulting and much improvement. This continued at a rapid pace, and the patient showed such amelioration that on April 28 he was discharged to the cardiac outpatient clinic with compensation completely restored. He continued to attend the clinic at irregular intervals, using digitalis as advised. He was readmitted to our hospital service on Aug. 20, 1938. Digitalis was increased. On August 24 1 cc. of Esidrone was given intravenously. A pronounced diuresis ensued, and he requested discharge on August 26, promising to attend the cardiac clinic.

His next admission occurred on Oct. 8, 1938, again with decompensation. The same routine was instituted but on Oct. 11 2 cc. of Esidrone was given with 4,900 cc. urinary output, and much improvement in his clinical symptoms. He was discharged Oct. 19, 1938, edema free.

His last admission occurred on Nov. 6, 1938, with anasarca and severe symptoms. The digitalis, morphine and atropine

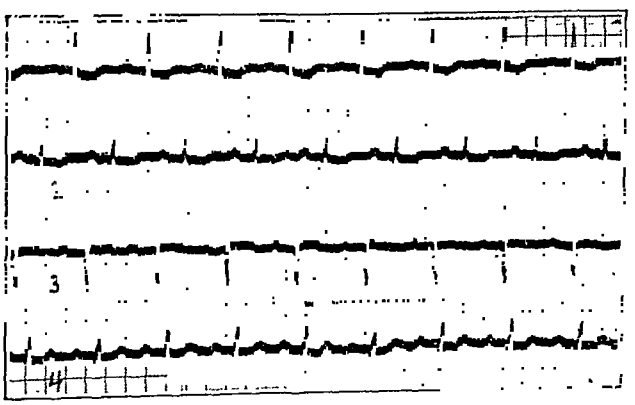

Fig. 2 (case 2).—Four lead electrocardiogram before injection of intravenous mercurial.

were given as before on his previous admissions. Esidrone 1 cc. was injected intravenously on November 8 and 2 cc. on November 11. Good diuresis was obtained. On November 15 a recheck electrocardiogram (fig. 2) was made just prior to injection of 2 cc. of Esidrone, administered intravenously at a rate similar to all other injections. Attention is directed to the PR interval of 0.22 second present prior to the injection. Within a few seconds after the injection the patient became extremely restless and decidedly dyspneic, with a rapid, weak, irregular pulse. The electrocardiograph was rapidly attached to the patient and a four lead tracing taken (fig. 3) showing the ventricular fibrillation. Death ensued a few minutes after the injection. Five injections were given intravenously to this patient prior to the last injection and two of the five were of equal potency to the dosage of the final injection.

CASE 3.—In a series of studies on diuresis produced by mercurials injected intravenously, as previous publications have indicated, the methods included repeated and frequent electrocardiographic tracings. One study embraced the immediate effect of the mercurial injection on certain cardiodynamic records. One method of procedure included the immediate action of the drug on the electrocardiographic tracing, necessitating

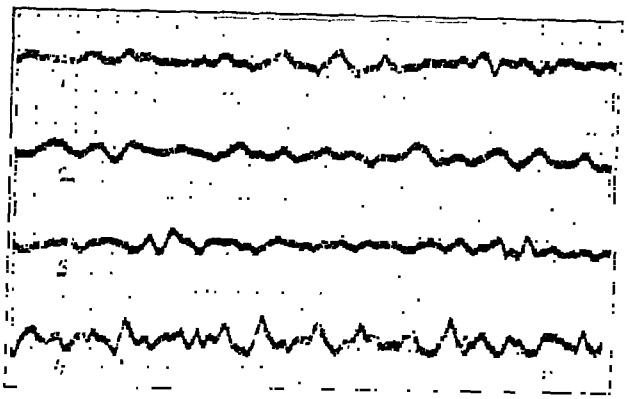

Fig. 3 (case 2).—Ventricular fibrillation about three minutes after intravenous injection.

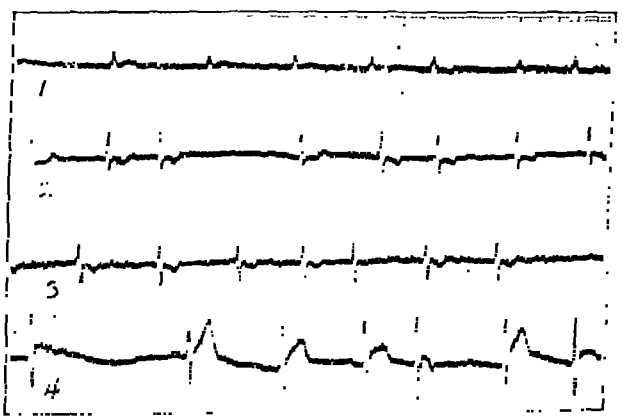

Fig. 4 (case 3).—Four lead electrocardiogram immediately before intravenous injection.

continuous attachment of the patient to the electrocardiograph through lead or derivation 2. This patient was number 76 in a series studied on this particular investigation and the injection was number 1438, many of which were injections on private patients, a few even injected in the office on ambulatory cardiac patients. This introduction to case 3 is given to indicate that we were prepared to take continuous tracings, which were done in the unfortunate case to be described, surprised and excited as we were at the disastrous episode.

A white woman aged 69 was admitted on March 12, 1940 with an examining room diagnosis of organic heart disease with decompensation. She gave a history of dyspnea, orthopnea, cough and edema of long duration. The dyspnea first appeared on exertion and subsequently became severe with pronounced nocturnal attacks. The past history revealed no evidence bearing on her present complaint, nor did an inventory of the various systems indicate any important additional complaint.

The patient was well preserved and weighed about 165 pounds (75 Kg.). She sat up in bed because of difficulty in breathing. The temperature was 97 F., the respiratory rate 44. She had a very irregular pulse of auricular fibrillation with a rate of 140 and a blood pressure determination of 160/110. The left heart border extended beyond the left anterior axillary line in the sixth intercostal space; the heart sounds were clear, with the irregular character of auricular fibrillation, very rapid, 125 per minute, with a systolic murmur at the apex. There was flatness at the right base, indicating fluid and congestive rales throughout the chest on both sides. The liver extended three fingerbreadths below the costal margin and was decidedly tender. There was an extensive edema of the lower extremities. The laboratory studies revealed on urinalysis a specific gravity of 1.020, albumin a trace, sugar a trace, epithelial casts and 1 to 5 pus cells per field. The nonprotein nitrogen was 3.1, creatinine was 2.3 and blood chlorides were 445 mg. per hundred cubic centimeters. The Kahn reaction was negative. Hemoglobin was 92 per cent. Red blood cells numbered 4,920,000 and white blood cells 11,600, with 76 per cent polymorphonuclears. The chest film revealed pronounced left ventricular enlargement and pulmonary congestion, with evidence of fluid in the right chest. The diagnosis was hypertensive and arteriosclerotic heart disease with pronounced hypertrophy and congestive heart failure. The patient was given 200 mg. of digitalis three times a day, ammonium chloride 2 Gm. three times a day, fluid restriction, and morphine and atropine for sedation.

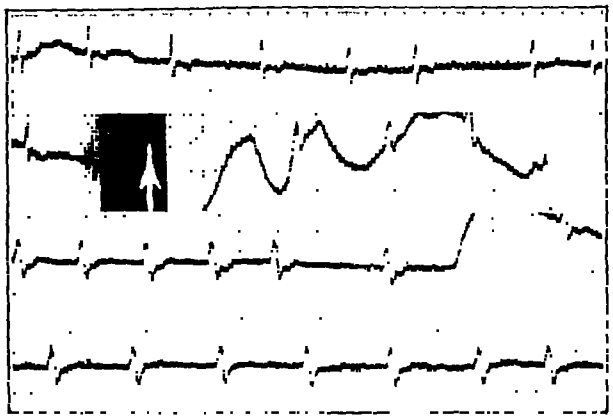

Fig. 5 (case 3).—Entire chart and all subsequent tracings are lead 2 derivation. The injection was made after the control tracing lead 2 in uppermost row. The arrow indicates the time of the intravenous injection. The machine was continuously connected to the patient and all the tracing represents a lead 2 connection. The text describes the sequence of events.

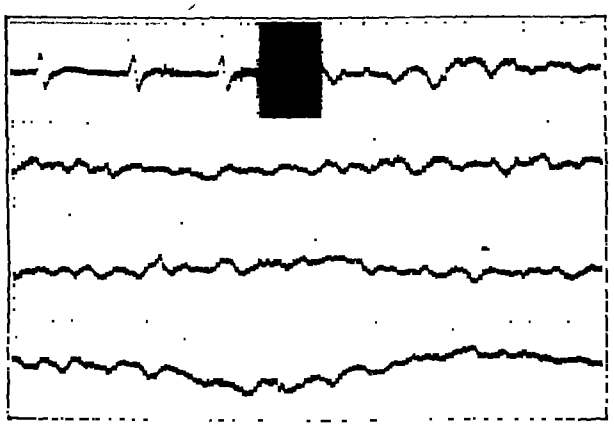

Fig. 6 (case 3).—Change to ventricular fibrillation.

On March 16 the heart and pulse rate had dropped appreciably, but the symptoms, chest signs of fluid, and the edema were not much improved. An injection of a mercurial was decided on to hasten improvement. The preliminary electrocardiographic four lead tracing and a tracing of lead 2 were taken before the mercurial diuretic Esidrone 2 cc. intravenously was given. The instrument was shut off for the injection and then turned on. Immediately on injection, which

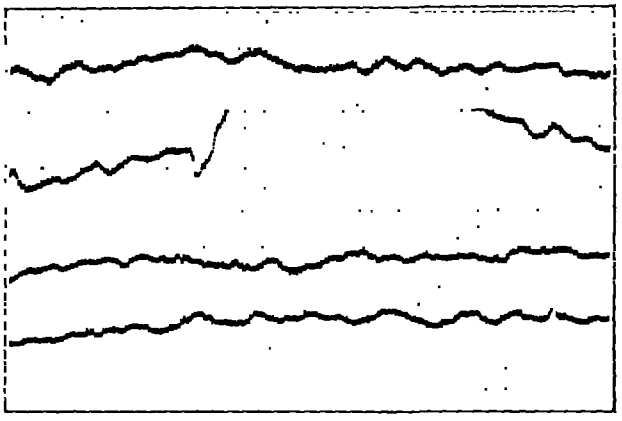

Fig. 7 (case 3).—Gradual weakening of cardiac ventricular action.

was rapid, the patient complained of chest pain, became acutely dyspneic, lost consciousness and moved excitedly in the bed. The instrument was still connected and throughout the entire episode was run on lead 2. There were a few short interruptions while the mechanical motor was being wound. The train of events can be described by a discussion of the electrocardiograms. Figure 4 is the four lead electrocardiogram with evidence of auricular fibrillation, an irregular ventricular rate of 80, low voltage R_1, almost isoelectric T_1, depressed ST interval in 2 and 3 with diphasic TS and S in 2 and 3. The influence of digitalis is accountable for most of this evidence. In figure 5 the first top tracing is the control lead 2 electrocardiogram. The tracings are all lead 2 derivations until the termination of the episode. Shortly after the beginning of the second tracing Esidrone 2 cc. was given intravenously, the instrument being turned off for the injection and then immediately started again; the patient began moving, accounting for the straying of the beam, but two things are immediately discernible: first, the ventricular complexes have changed their appearance, now having a duration of 0.15 second compared to 0.06 second, the ST junction has dropped 2 mm. and the

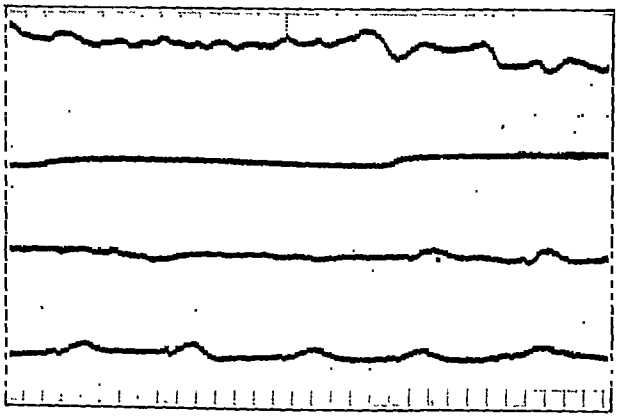

Fig. 8 (case 3).—Almost complete standstill except in bottom tracing, where the movements represent QRS complexes.

T is almost isoelectric. The QRS complexes are more equally spaced at first, 0.64 second, then gradually extending to 0.84 second, until in figure 6 in the first tracing there is a change to ventricular fibrillation, which continues throughout all lead 2 tracings on this chart, with figure 7 indicating a gradual weakening of the cardiac ventricular action and almost heart

standstill in figure 8, until the bottom tracing, when some type of rhythmic activity is noted. This action occurs at 1.2 seconds approximately fifty times a minute. These represent QRS complexes; in figure 9 the deflections succeeding these small QRS movements are T deflections. In figure 10 these small deflections appear rhythmically closer at 0.56 second intervals, gradually subsiding, so that in the first tracing of figure 11 there is cardiac standstill. An injection (at *A*) into the heart of

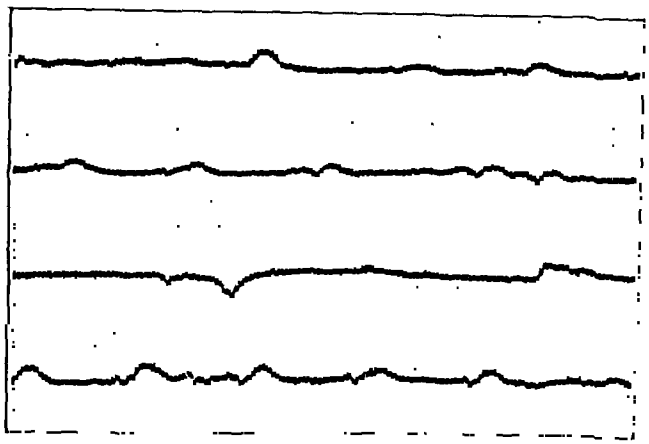

Fig. 9 (case 3).—QRS movements are followed by T deflections.

1 cc. of 1:1,000 epinephrine was followed for twenty-eight seconds with no evidence of cardiac activity in the tracing. The second tracing in figure 11 was a continuation of the twenty-eight second tracing and shows a ventricular impulse followed by a 6.26 second cardiac standstill, then seven similar S deflections with a sudden reversal to upright R complexes with gross notching, each having a duration of approximately 0.2 second. The bidirectional variation of the ventricular complexes does not alter to any significant degree the individual contours. The intraventricular conduction deformity persists. This continues through the first tracing of figure 12 and the initial portion of tracing 2, when cardiac standstill of 1.8 seconds occurs, followed by a single ventricular extrasystole. These upright ventricular complexes are rhythmic, occurring at 0.6 second intervals. They can be interpreted as evidence of a slow ventricular rhythm similar in form to a ventricular

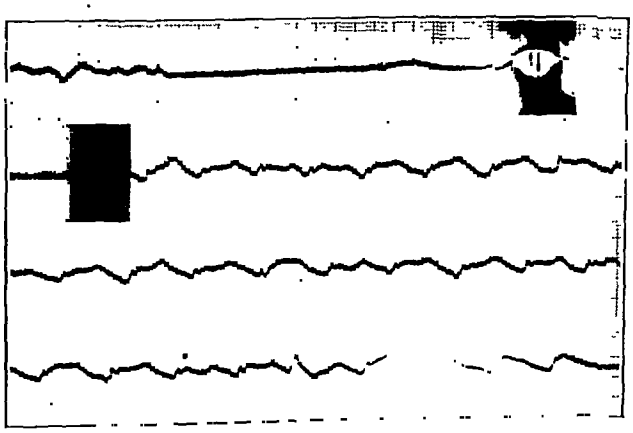

Fig. 10 (case 3).—The small deflections gradually subside.

tachycardia or flutter or parasystole at a rate of 100 impulses per minute. The contour changes again in the third strip, with gradual weakening in figure 13 with long periods of cardiac standstill. The last line of the tracing in chart 10 was continued for fifty-eight seconds and the patient was pronounced dead.

COMMENT

In the review of the clinical reports published it must be noted that many of the deaths occurred in individuals who had received several to many injections of the drugs intravenously. No deaths were found following intramuscular injections, similar to the findings in our first 2 cases. The deaths occurred more frequently when the larger doses were employed. The drugs are dispensed in a 10 per cent solution, 1 cc. giving 100 mg., containing from 35 to 43 mg. of mercury in the different drugs. Thus twice the amount of mercury is used in the larger doses.

Several observers have published electrocardiographic evidence in the experimental observations. Barker, Lindberg and Thomas reveal in detail the changes appearing in the experimental electrocardiogram. The tracings which we demonstrate are the only ones which we have been able to find in the published reports of the sudden deaths.

Experimental evidence does not support the view that sensitization is the mechanism whereby the "shock" dose produces death. Dr. Macht [14] attributes the sudden death after intravenous injection to intravascular clotting. This point of view would emphasize the contributory factor of increased clotting property produced by digitalis when digitalis is being used. Thus Dr. Macht suggests the use of an anticoagulant such as heparin prior to the intravenous use of the mercurial diuretic.

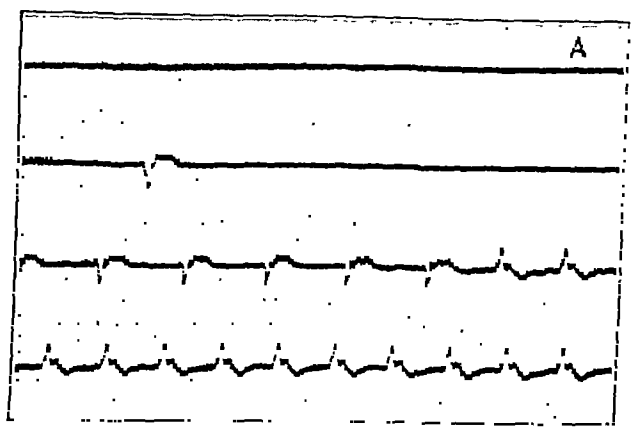

Fig. 11 (case 3).—Cardiac standstill, injection (at *A*) of epinephrine 1 cc., ventricular impulse in second tracing, S deflections in third, followed by reversal to upright R complexes.

Most clinical and experimental evidence points to the direct action on the heart by the mercury ion. Where intraventricular conduction deformities are so constant in the experimental evidence any degree of block should be carefully studied before using the intravenous route of administration. A more careful attitude to the weight: dosage ratio should be observed and the large doses in the small patient probably should not be employed.

It is impossible at the present time to predict which particular injection carries the danger of sudden death. There is no evidence that dilution, slow rate of injection or smaller dosage or prior atropinization will prevent the fatalities. No reports of sudden death have been found from deep intramuscular injection or the rectal or oral use of these substances, although focal abscess at the site of the injection has been experienced and gastrointestinal complications have been met. The other objections to oral, intramuscular or rectal use of the organic mercurials are well established in addition to the more frequent unsatisfactory diuretic results when compared to the intravenous injections.

14. Macht, D. I.: Personal communication to the authors, May 10, 1944.

SUMMARY AND CONCLUSIONS

1. Three patients died suddenly after intravenous injection of a mercurial diuretic. One patient received mercupurin and two Esidrone.

2. Each of the 3 patients received the dose of 2 cc., representing 200 mg. of the drug and 78 mg. and 66 mg. and 86 mg. respectively of the mercury.

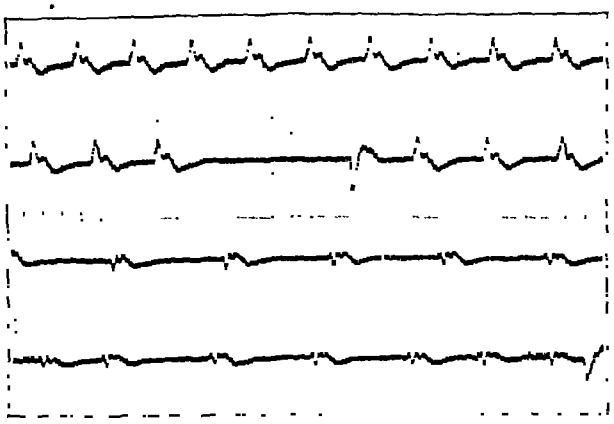

Fig. 12.—Cardiac standstill of 1.8 seconds in second tracing followed by a single ventricular extrasystole. Upright ventricular complexes, the contour changing in the third strip.

3. Two patients had received prior injections of the mercurial diuretics before the fatal episode. There were no reactions to these prior injections.

4. Electrocardiographic studies are available in 2 patients with tracings shortly before and during the reactions.

5. Both patients showed the development of ventricular fibrillation following the drug.

6. In 1 patient an almost continuous electrocardiogram was obtained with lead connection 2 attached. The resulting electrocardiogram showed changes very similar to the experimental electrocardiogram reported

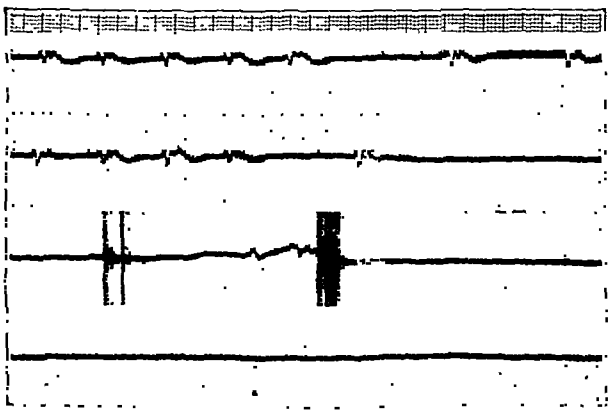

Fig. 13 (case 3).—Gradual weakening, with periods of cardiac standstill.

in the anesthetized dog, such as the changes in the ST junction and the ST interval, the intraventricular conduction deformity and changes in the T waves.

7. Ventricular tachycardia did not occur in the patient with the continuous tracing, although ventricular rhythm of a bidirectional character was noted.

8. Ventricular complexes were resumed after cardiac standstill by intracardiac injection of epinephrine.

9. Intravenous injection of mercurials should not be discontinued, but the realization of danger of their use must be ever present. This is in addition to four such possible other dangers as the dehydration syndrome, the depletion of chlorides, the disturbance of the electrolytic balance and the sudden mobilization of large amounts of digitalis from the edema fluid.

10. The disadvantages of the other avenues of administration should be weighed against the danger of sudden death from intravenous use.

ABSTRACT OF DISCUSSION

DR. JOHN W. SCOTT, Lexington, Ky.: What Dr. Volini and his associates have described is not unrelated to the shock often seen in these patients twelve to twenty-four hours after the injection of the drug. I have had an interesting experience with patients who had suffered such shock to an extent that 1 patient was unwilling to continue the drug. There were 3 of these, all in the seventh decade, 2 with rheumatic heart disease, mitral stenosis and auricular fibrillation, the third with thyrotoxic heart disease and coronary sclerosis. A lyophilized vitamin B preparation, recently introduced, was dissolved in 2 cc. of mercupurin. This immediately yields a crystal clear solution. Given intravenously, diuresis was unimpaired; there were no untoward symptoms. There was freedom in 2 of the patients from the shock which had been disturbing. In the third, distressing muscle cramps, which regularly occurred the night following the injection, were abolished. This method has been used fifty or sixty times on the 3 patients with not a single unfavorable occurrence. It is planned to use some of the components of the B complex singly in order to determine whether one or more than one is responsible for this effect. The action of the diuretic thus modified is more smooth and no less effective.

DR. ITALO F. VOLINI, Chicago: The distinction should be made between speed shock and the collapse or exhaustion subsequent to the injection, as indicated in the twenty-four hour period following an injection. Poll and Stern have indicated that many persons suffer from considerable chloride depletion. This can be combated by giving the patient chlorides. Usually the ammonium chloride which is administered will maintain the chloride balance up to the level that is desired. Of course, most of these patients are seriously ill and many things can happen. Some of them develop vasospastic or even organic encephalopathies; following the injection many of them become quite exhausted. It favors thrombosis. Some even, as attention is called to this in the literature, develop symptoms of renal insufficiency with the development of uremia. One has to be careful in the prediction of prevention of symptoms of shock and define what is meant by shock before one can state that any type of therapy will prevent such a mechanism. In speed shock in the experimental animal the signs of anaphylaxis are frequently found. One finds the evidence of incoagulability of the blood.

Neurotic Conflict Between the Individual and Society.—With its fondness for cults, the world in the past few decades has reared temples to the gods of the normal. The cult of normalcy has gathered about itself priests and prophets who loudly exhort all who would be saved to worship at the shrine of perfection. Apostles swarm the land and invoke the spirits of science in their zeal to bring balm to those unfortunate souls who cannot fit into the Procrustean bed of their own making. Mental hygiene and physical hygiene and spiritual hygiene and political hygiene and a host of other kinds of hygiene are fervently broadcast and foretell the coming of the millennium. The great gods have proclaimed it: all shall be of one measure, all shall be normal. All conflict shall cease, and the soul shall be at peace with itself and the world. Mirabile dictu. —Wechsler, I. S.: The Neurologist's Point of View, New York, L. B. Fischer, 1945.

ADMINISTRATION OF PENICILLIN BY RECTAL SUPPOSITORY

PRELIMINARY NOTE

LEO LOEWE, M.D.
ERNA ALTURE-WERBER, PH.D.
AND
PHILIP ROSENBLATT, M.D.
BROOKLYN

Many investigations are being pursued in an effort to circumvent the parenteral administration of penicillin. Several reports [1] indicate the feasibility of oral administration by elimination of the destructive action of hydrochloric acid in the stomach. In general, it requires a fivefold increase in dosage to achieve penicillin serum assays comparable to that obtained by intramuscular injection. The conjoint use of retarding agents has in some measure prolonged the effects of the individual dose.

The rectal administration of penicillin has not been attempted, probably because of the assumption that the presence of the penicillinase-producing colon group of organisms might serve as an impenetrable barrier. Despite our own misgivings in this direction, experiments were undertaken to explore the possibilities of rectal administration because of its simplicity, the wide latitude in the selection of adjuvants and the obvious clinical advantages. Probatory results have been so promising as to merit this preliminary report.

Varying amounts of the sodium salt of penicillin [2] were incorporated by hand in a simple cocoa butter base. Suppositories were inserted rectally without any previous preparation in hospitalized in-bed patients, selected at random, and in healthy ambulatory volunteers. The 14 subjects were instructed to retain the suppository, which caused little, if any, momentary discomfort. Blood samples were withdrawn hourly for twelve hours and after twenty-four hours for penicillin assays.[3]

The results following a single dose penicillin suppository are presented in the table. Appreciable penicillin blood titers were obtained in 12 out of 14 instances. Effective levels were found after twenty-four hours in 2 instances and for four to twelve hours in an additional 7 subjects.

Correlation between dosage and penicillin levels was not entirely consistent in this limited experience with crude material. Maximum levels up to 0.768 Oxford unit per cubic centimeter of serum were obtained with the million Oxford unit dosage. Prolonged minimum levels of 0.012 Oxford unit per cubic centimeter were observed with all dosages employed. In interpreting the results and establishing subsequent procedure it is noteworthy that the five most unsatisfactory results—including the two blanks—all occurred in the ambulatory volunteers. The most sustained effects were noted in hospitalized recumbent patients.

Work is in progress to revise the technic of administration, including the preliminary preparation, the adoption of an ideal retarding base and the use of other salts of penicillin, in order to achieve optimum results.

Penicillin Blood Levels—Oxford Units

* A indicates ambulatory healthy volunteers. † R indicates recumbent hospital in-bed patients selected at random.

The sustained minimum serum titers of 0.012 Oxford unit per cubic centimeter are effective against the gonococcus, pneumococcus and hemolytic streptococcus. Clinical trials in patients with gonorrhea, pneumonia and tonsillitis are projected.

SUMMARY AND CONCLUSIONS

Prolonged, effective penicillin blood levels have been obtained following the administration of penicillin by rectal suppository.

177 New York Avenue, Brooklyn 16.

Aided by grants from friends of the Hospital and the Dazian Foundation for Medical Research.

Leprosy in China.—Leprosy is widespread over China, from Manchuria in the north to Kwangtung and Hainan Island in the south and from the province of Chekiang on the east to that of Sinkiang on the west. It is estimated that more than a fourth of the world's 4,000,000 lepers are found in China. At least half of the people of China live in areas in which leprosy occurs. Hospitals and facilities for the treatment of lepers are entirely inadequate. In 1937 only twenty-seven leprosariums, with 4,050 beds, were operating in China.—Simmons, James S., and others: Global Epidemiology, Philadelphia, J. P. Lippincott Company, 1944.

THE Rh FACTOR AND THE PUBLIC HEALTH LABORATORY

FREDERICK P. LEE, M.D.

ANNA I. VAN SAUN
Director

AND

EVELYN L. BROWN. B.A.

PATERSON, N. J.

At first glance it would seem that the usefulness of the public health laboratory for Rh factor determinations might be open to question. Certainly it would not have occurred to us to enter a field which up to very recently was rather preempted by hospital laboratories and very few of those.

Our entrance into this somewhat unusual field was due to a request from the Maternal Welfare Committee of the Passaic County Medical Society. One of our largest hospitals was not ready to take on the added burden of Rh determinations for its blood bank and it was suggested that we do this work for them. It was also suggested that, since we received a very large number of specimens for premarital and antepartum Wassermann tests, we should perform Rh determinations on these specimens. Accordingly, after a preliminary period of study we began this work as a routine in June 1944. Blood grouping was also added, since marital blood incompatibility sometimes is due to a difference in blood groups too.

Nearly 3,000 blood specimens have been tested, the great majority of them ante partum. We soon found that there simply was not enough testing serum to include premarital specimens and but 616 of these were tested, of which 12 per cent were Rh negative.

Approximately 15 per cent of the specimens received from antepartum sources were Rh negative. All Rh negative specimens were retested with at least three different serums secured from different sources, and those giving anomalous results were checked by Dr. Philip Levine in his laboratories at Linden, N. J. We feel that checking negatives with several serums is of the highest importance.

We also request a specimen of blood from the husband of each Rh negative woman. The obstetrician secures this for us. Thus far each husband has been cooperative with the exception of 2, who could not see that they had anything to do with it! Of 98 husbands tested, 80 were Rh positive and 14 were Rh negative. The husbands of 4 Rh positive women were Rh negative. Prospects for an Rh negative woman to secure an Rh negative husband are not very brilliant, it would seem. No doubt many more Rh negative husbands would have been noted had all husbands of our antepartum patients been tested.

Of 749 specimens which have been tested for the hospital blood bank 14 per cent were Rh negative, thus forming a nucleus for the hospital's Rh negative donor's club.

The county medical society receives a copy of all our Rh negative results with name and address of the patient. This looks to the formation of a County Rh negative Donor's Club. Of course many of the antepartum patients could not at present be used as donors, but on the other hand the list of usable donors grows.

Seven cases of erythroblastosis have come to our attention through this work. All of the mothers were Rh negative with one exception. All of the fathers were Rh positive. All the babies were Rh positive. The one exception to the Rh negative mothers could not be explained. Father, mother and baby were Rh positive, though the infant was definitely erythroblastotic. Three of the babies lived, as the result of appropriate treatment with transfusions of Rh negative blood. The child of the Rh positive parents died.

But one mother of an erythroblastotic infant developed any appreciable amount of agglutinin.

The members of the Passaic County Medical Society, especially the obstetricians, are well satisfied with the results of our experiment and apparently wish it to be continued.

From the Division of Laboratories, Board of Health, Paterson, N. J. Assistance and suggestions were received from Dr. Alexander Wiener of New York, Dr. Philip Levine of Linden, N. J., and Dr. Theodore Graham and other cooperating members of the Passaic County Medical Society.

Clinical Notes, Suggestions and New Instruments

LOW TEMPERATURE THERAPY FOR PRESERVATION OF LIMBS

ISIDOR KROSS, M.D.
Clinical Professor of Surgery, New York Medical College, Flower and Fifth Avenue Hospitals
NEW YORK

There has recently appeared in the literature an article[1] in which refrigeration anesthesia in surgery is discussed from both the experimental and the clinical point of view. The character of this work on the whole is of such high grade that if all of the author's conclusions are accepted without question or challenge it will cause an unnecessary delay in the application of a therapeutic measure that has proved itself beyond any doubt to be of great value in surgery of the extremities. In the body of the paper the statement is made that "cooling per se does not seem to have a beneficial effect on an inflammatory process. While the infected part is cooled there is an inhibition not only of bacterial growth and toxin production but also of the normal tissue response. Release from the cooling may aggravate the eventual inflammatory response." In the summary the further statement is made that "it was hoped that refrigeration might enable us to preserve the vitality of many limbs suffering from those afflictions which would ordinarily have to be sacrificed. Bacterial growth is retarded by refrigeration, but so also is the tissue response to inflammation, and on the release of the cooling the inflammatory reaction may be even aggravated."

The experience that has been acquired at City Hospital with the use of low temperature treatment, as introduced and originated by Drs. Frederick M. Allen and L. W. Crossman,[2] is so contrary to the assumptions and to the theoretical conclusions that have been drawn by Dr. Richards that the following case is presented:

REPORT OF CASE

Mrs. H. P., aged 57, admitted to the medical service of Dr. A. B. Cannon at the City Hospital on April 18, 1943, had been suffering from a chronic osteoarthritis of the right knee

From the surgical department, City Hospital.

1. Richards, V.: Refrigeration Anesthesia in Surgery, Ann. Surg. **119**: 178, 1944.

2. Allen, F. M.: Reduced Temperatures in Surgery. Am. J. Surg. **52**: 225, 1941. Crossman, L. W.; Ruggiero, W. F.; Hurley, V., and Allen, F. M.: Reduced Temperatures in Surgery: Amputation for Peripheral Vascular Disease, Arch. Surg. **44**: 139 (Jan.) 1942.

for the past four years. Her family history was negative. About six weeks before her admission to the hospital she warmed her feet near an oven and on the next day she noticed a blister on her left knee. A few days later this blister opened spontaneously and discharged a yellow watery fluid. Shortly thereafter the skin on the anterior surface of the leg became red, macerated and excoriated. Examination at the time of admission showed that the skin on the anterior surface of the left leg was red, edematous and macerated. There were irregular patches of necrotic tissue throughout this area. The patient was put on sulfadiazine therapy. On April 25 an urticarial rash developed on the forearms and on the face. This was associated with pruritus and was diagnosed as a drug rash. The chemotherapy was discontinued. In the meantime, in spite of the sulfadiazine treatment, the local condition had become much worse. The necrotic tissue had increased in extent and the adjacent inflamed tissue had become widely undermined and was bathed in pus. Treatment with zinc peroxide was now instituted. During all this time the temperature of the patient was septic.

On May 3 the attending physician advised a midthigh amputation as a life saving remedy and requested surgical consultation. At this time, as surgical consultant, I noted that the patient had an extensive necrotic suppurative cellulitis of the right foot and leg. There was complete absence of cutaneous tissue on the anterior aspect of the leg extending from the junction of the upper and second quarters above to the junction of the third and fourth quarters below. This area extended inward to the posterior aspect of the limb. The tissue external to this area was gangrenous in the lower half of the leg and spottily gangrenous in its upper half. The remaining skin was extensively undermined in all directions. The entire inflamed area was covered by a very foul smelling exudate. The tissues above the infected area extending into the thigh were very edematous. In answer to the question of therapy, an amputation through the thigh would be synonymous with cutting through highly infected tissues resulting either in local stump gangrene or probably general sepsis. For this reason I considered amputation at this time contraindicated. The choice appeared to be between chemotherapy and low temperature treatment. The patient had had chemotherapy while in the medical ward, but the infection continued to spread. For this reason an attempt was to be made to treat the condition with refrigeration. The prognosis was grave. The patient was transferred to the surgical ward and the treatment was instituted.

May 8, twenty-four hours after the application of the treatment, the body temperature had been normal and the odor of the discharges was now entirely gone. There had been a definite regression of the cellulitis, and the general condition of the patient was considerably better.

May 12, for the past twenty-four hours the extremity had been in the air chamber (in this apparatus the temperature of the limb can be kept at the required low level and the uncovered limb can be observed at all times and all changes can be noted). On inspection this morning the air chamber was found to be operating imperfectly, so that the required low temperature had not been maintained. The temperatures in the air chamber and in the room were the same. The limb this morning showed a pronounced reactivation of the infection and was hot to the touch. The patient felt considerable pain in the limb and her body temperature had risen to 102 F. The limb was to be placed back into the refrigeration blanket.

May 14 the acute character of the infection noted previously appeared to be under control, and the body temperature was normal this morning.

June 1 the refrigeration treatment had been discontinued forty-eight hours before in order to determine the natural status of the limb without treatment. This was followed by a recurrence of the active inflammation. Gangrene had developed in the three outer toes, and the general body temperature had risen to 102.2 F. We could not tell whether the infection had been fully controlled, and treatment was stopped as a test measure. The treatment was to be resumed and as soon as the infection was under control a midthigh amputation was to be done. It appeared that the virulence of the infection was so intense that it was controlled only during the exposure of the limb to the low temperature and recurred as soon as the normal room temperature obtained. For this reason it was felt that the proper procedure would be to obtain control of the infection and to amputate when that time had been reached.

June 7 it was observed that since resumption of the refrigeration treatment the body temperature had been normal. The general condition of the patient was now satisfactory and the local condition had improved very perceptibly. The gangrenous areas on the toes were beginning to separate. The other gangrenous areas on the limb were also beginning to separate, and the inflammation of the surounding skin had subsided to a considerable extent. If this improvement continued, it was felt that very possibly an amputation might be avoided and that the limb might be saved. The treatment was to be continued with this in view.

June 21 the foot was still covered with an extensive necrotic slough extending from all the toes half way up the dorsal and plantar surfaces. The two outer toes were completely necrotic. The other toes appeared viable and could be made to move voluntarily. The ulcerated areas of the leg and thigh were clean and were beginning to show small areas of newly formed islets of epithelium. The results so far were really remarkable and could be laid to the door of the continuous refrigeration treatment.

By July 28 the patient's right lower extremity had been exposed to refrigeration therapy for eighty-nine days continuously. With the exception of a small superficial slough on the inner aspect of the big toe and a slightly larger dry slough on the inner aspect of the ankle, the limb showed a complete absence of inflammation. The ulcerated areas were clean and were lined with abundant healthy granulations. Islands of new epithelium were scattered throughout the granulation tissue and new epithelium was growing in from the outer edges of the ulcerated areas.

In view of the unexpected reparative progress that the patient had made, it was decided to discontinue the refrigeration treatment, because it now seemed to be perfectly safe to do so without any fear of a lighting up of the infection. From now on to the time of her discharge from the hospital, healing progressed rapidly and the ulcerated areas, for which skin grafting had been planned when the infection had cleared up, showed such rapid epithelization that this procedure was held in abeyance until the full effect of the spontaneous healing could be seen.

On June 2, 1944 all the ulcerated areas were completely covered with newly formed epithelium. The heel was now also completely healed. The patient had an osteomyelitis of the tip of the heel with sequestrum formation. This was treated expectantly. The dead bone was extruded spontaneously, granulation tissue grew over the exposed bone and new epithelium in turn grew over the granulations. On October 16 the patient was transferred to the municipal hospital for chronic diseases for the treatment of her osteoarthritis.

COMMENT

This case report is published because it is, as far as I know, one in which refrigeration or low temperature treatment was employed for the longest period of time on record, with the successful preservation of a limb that under ordinary circumstances would have been amputated. It also shows the necessity of continuing with the treatment until the infection is fully and completely overcome.

Special Articles

The Committee on Standards of the Scientific Advisory Committee of the National Foundation for Infantile Paralysis recently reported to the Advisory Committee the results of a study made on the evaluation of different methods of treatment on the after-effects of poliomyelitis. The report is published in THE JOURNAL *with a view to indicating to physicians who are responsible for the care of such patients the standards that should prevail in drawing conclusions as to the results accomplished.*—ED.

EVALUATION OF THE RESULTS OF TREATMENT IN INFANTILE PARALYSIS

RUSTIN McINTOSH, M.D., CHAIRMAN; CARL E. BADGLEY, M.D.; RALPH K. GHORMLEY, M.D.; DON W. GUDAKUNST, M.D.; ANDREW C. IVY, MD.; HOWARD T. KARSNER, M.D.; ROGER I. LEE, M.D., AND HENRY R. VIETS, M.D.

In taking note of its assignment to set up standards by which to evaluate the end results of the different methods of treatment of the after-effects of poliomyelitis, the Committee first made an effort to define the boundaries of its task.

In the present state of our understanding of poliomyelitis the uncertainty of diagnosis is well recognized, and it is a matter of common knowledge that any large series of cases, whether they were gathered during an epidemic or in interepidemic times, may reasonably be supposed to include examples of other diseases. The first requisite of evaluation, then, accuracy of diagnosis, is approachable but not ideally attainable.

A second requisite for the fair comparison of two forms of treatment is equal sampling of cases. In this respect poliomyelitis affords unusual difficulty. The expression of the infection varies in any epidemic from negligible or even undetectable symptoms in one patient to a rapidly fatal issue in another. A patient who is totally incapacitated at the height of his infection may recover so rapidly that within a few weeks no appreciable residuum persists. Injustice is done when one investigator, including in his series a number of early cases, claims credit for his results when compared with those of another investigator whose series comprises only cases showing residual paralysis two weeks or more after onset. In selecting clinical material for the evaluation of many of the manifestations of poliomyelitis it appears necessary to include, in both the study and the control groups, cases of all types—not only those with residual paralysis or deformity, but also those in which no muscle weakness is detected.

Another aspect of the problem of sampling has to do with controls. If a particular method of treatment has received favorable notice in the public press and in radio broadcasts, failure to apply this method may arouse vigorous protest from patients or their parents. It then becomes difficult, if not impossible, to explore new methods by impartial comparison even though, in the light of our present knowledge, the variability in residual after-effects is governed to a greater extent by such factors as the age of the patient, the inherent character of the epidemic and other imponderables than by any therapeutic agent or practice which has thus far been put into our hands. Consequently, many of the claims advanced for the value of this or that therapeutic agent actually rest on evidence which fails to pass impartial examination.

On this question of controls, then, the Committee desires to put itself on record as being strongly in favor of the adoption in the field of the alternate case method, particularly the alternate paired case method, with age, severity of the attack and extent of paralysis being taken into account whenever any method of treatment is to be appraised.

A broad concept of the evaluation of therapeutics in poliomyelitis must take account of all the sequels—physical, psychic and social—and treatment should be directed at all of these disorders; but, for comparison of the effects of different forms of treatment, paralysis and deformities are selected for study because they are subject to objective measurement. The Committee strongly urges that an objective assessment of muscle strength be obtained in each case studied at the earliest period in the course of the disease at which such an examination can be carried out with reliable accuracy and without detriment to the patient.

The Committee recognizes the desirability of attaining quantitative measurement in the setting up of standards. The problem, however, is not a simple one. The use of any dynamometer, even of a relatively simple device like Lovett's spring balance, demands cooperation from the patient, implies a constancy of the patient's attention and effort which is not always attainable, and is believed to be beyond the range of technical competence of all except those who have devoted considerable time to the actual application of such apparatus, whether they be technicians or physicians. Moreover, satisfactory standards of reference for different muscles at different patient ages and for different patient backgrounds in relation to nutrition, innate muscle strength, previous illness and so on are not available, and the error involved in the use of the contralateral member in the individual patient is only too obvious. While fully recognizing the desirability of perfecting methods of quantitative measurement of muscle function as a research project, the Committee believes that broad application of some such method as the spring balance technic will cloud the issue by implying an accuracy which does not exist.

It is therefore recommended that emphasis be placed on standardization of a scheme of muscle evaluation which can be widely applied by adequately trained physical therapy technicians, by orthopedists or by any physician willing to take the necessary training in the technic of the test. For the purpose of recording residual paralysis, common usage has demonstrated the resistance tests with and against gravity to be the most practicable. There is unanimity of use but diversity of nomenclature. The following terms are recommended as a standard to produce uniformity, and the following symbols are advised as a standard unit expression of muscle strength:

5 = N = Normal	= No apparent deficiency.
4 = G = Good	= Approximates normal but fatigues more readily.
3 = F = Fair	= Where part can perform function against gravity but is definitely weak.
2 = P = Poor	= Where muscle is so weakened that it cannot perform its function against gravity but with removal of gravity can function.
1 = T = Trace	= Where there is slight contractility of the muscle.
0 = O = Zero	= No evidence of contractility of muscle fibers.

Of these alternative symbols, the ciphers are held preferable to the initial letters for purposes of record because they are less subject to error in reading if the records are to be pooled for analysis.

The Committee has examined a number of record forms, or so-called muscle charts, in current use in different parts of the country and is still working on the design of a form which combines the advantages of all those studied. When this is completed, which is expected in the near future, the Committee proposes to submit its record form to the Committee on Publications with the recommendation that copies be made available for distribution through the Foundation. In this way it is believed that active interest in objective evaluation of the patient's status will be fostered and that comparison of groups of patients treated by different methods will be greatly facilitated.

The Committee gave some thought to that portion of its assignment which might be held to include the devising of new methods and technics of assessment of the status of a patient who exhibits some of the aftereffects of poliomyelitis. It was generally agreed that so-called "stimulation of research" on the part of committees is liable to be sterile, that the needs are well recognized by all competent investigators in the field, and that it rests in the nature of things that in the course of time, as new methods of mensuration become available, these will be tested out experimentally on patients with poliomyelitis with a view to their more general application. As a matter of record, the accompanying list is appended of various methods of assay which deserve further consideration in any intensive effort directed at improving the evaluation of a patient's status:

Methods of Assay

Loss of normal neuromuscular function	Electromyogram Chronaxia Response to measured intensity and frequency of sinusoidal current Response to galvanic and faradic stimulation
Incompetence of specific muscles	Vital capacity measurement (intercostals) Fluoroscopic evaluation of respiration (diaphragm) Cystometric measurement (disturbance of bladder function)
Atrophy of muscle	Volumetric measurement by oncometer Soft tissue roentgenograms Photography against a measured grid background
Atrophy of bone	Roentgenographic mensuration of length and thickness Roentgenographic measurement of density of calcification Photography
Emotional status with respect to the disease	Psychiatric evaluation

From a historical point of view, most of the contentions over the relative effectiveness of one or another mode of therapy have dealt with the manifestations evident at a comparatively late stage of viral invasion, at a time when the infectious agent either is firmly established or has already inflicted irreparable damage, whereas there is no argument whatever over the disappointing results of all efforts to kill the virus within the host or by artificial means to neutralize its attack. When a practicable and truly effective virucide at last becomes available to clinical medicine, as we may confidently hope will come to pass, then all efforts to set up standards for the evaluation of treatment of aftereffects may be expected to lose their point. With sulfadiazine and penicillin in the current armamentarium for the treatment of pneumococcic pneumonia one no longer hears any debate over the value of digitalis or whisky for patients with lobar consolidation.

THE COORDINATION OF MEDICAL AND BLUE CROSS PLANS

LOUIS S. REED, PH.D.
AND
HENRY F. VAUGHAN JR., A.B.
ANN ARBOR, MICH.

Voluntary prepayment plans are making a worthwhile contribution to health security and have important potentialities. Beginning in 1932 hospital service plans have developed to the point where there are seventy-eight of such plans in the United States, with an enrolment of over 16,000,000 persons. Before the end of the year it is likely that plans will exist in all states. At the present time in three states over 30 per cent of the population of the state is enrolled and in seven states between 20 and 30 per cent of the population are enrolled. In a number of urban centers—Cleveland, Ohio, Rochester, N. Y., Rockford, Ill.—to name a few, over 50 per cent of the population belong to the hospital service plan.

At the present time there are in operation nineteen medical service plans sponsored by local and state medical societies. These plans have a total enrolment of over 1,800,000. New plans are rapidly being organized in every section of the country, and enrolment in already existing plans is beginning to increase rapidly. Thus far almost all the medical service plans are limited to surgical and obstetric service, and, when these are not provided by the hospital plan, to x-ray, laboratory and anesthesia service in connection with hospitalized cases. The proper actuarial basis for these limited services has been established or is being rapidly established. A workable pattern of administrative technics seems to be in process of crystallizing. In short, it looks as if medical service plans are at about the same stage of development as hospital plans were in 1936 or 1937 and that a rapid growth of these plans paralleling the development of hospital plans is to be expected.

One of the most important problems which must be solved if medical and hospital plans are to achieve their full potentialities is that of their proper coordination with each other. On this point there are offered the following observations based on a survey of prepayment plans which we have been conducting for the U. S. Public Health Service. In the course of that survey thirty-eight of the Blue Cross and all but two of the medical plans were visited.

RELATIONSHIPS BETWEEN MEDICAL AND HOSPITAL PLANS

In general, there are four types of relationships to be found between the medical and hospital plans.

A. *No coordination.* Each plan is separate and distinct and there is no coordination of their activities.

B. *Separate corporations, separate executive directors and to some extent separate administrative staffs.* Each plan performs certain functions for itself, notably approval of claims, payment of hospitals or physicians and maintenance of relations with hospitals or physicians. One plan contracts to perform certain other functions, usually enrolment, billing and record keeping, for the other, or there is joint control of these functions.

C. *Separate corporations and separate boards of directors but a single executive director with one administrative staff.* The medical plan is administered by the

From the Division of Public Health Methods, U. S. Public Health Service.

Blue Cross plan. The medical plan has no employees of its own; the two plans are separate only in their policy making bodies.

D. *One corporation.* One organization with a single board of directors offers both hospital and medical service.[1]

The accompanying table lists the present medical plans, shows their present membership, last year's growth, the ratio of medical plan members to Blue Cross plan members, the percentage of the population of the area enrolled in the medical plan, and the type of relationship with the Blue Cross plan or plans in its area.

The table shows that, of the nineteen plans,[2] two plans with a total of 308,000 members have arrangement A, no coordination with the Blue Cross plans in their area. California Physicians' Service has arrangement A with the Blue Cross plans in the northern part of the state and arrangement B with the Blue Cross plan in the southern part of the state. Arrangement B is held by three plans, Michigan, New Jersey and Pennsylvania, with a total of 822,000 members. Nine plans with a total membership of 327,000 have arrangement C and four plans with a membership of 135,000 have arrangement D. It is noteworthy that all the plans started in the last two years have either arrangement C or arrangement D.

The common goal of the Blue Cross and the voluntary medical plans should be to give protection against the costs of illness to as many people as possible. Which of the four possible relationships will facilitate the achievement of this goal most quickly and effectively?

Medical Service Plans: Year Started, Present Membership, 1944 Growth, Ratio of Members to Blue Cross Plan Members, Percentage of Population Covered and Type of Arrangement with Blue Cross Plan

Name of Plan	Area Served	Year Started	Membership 1/1/45	Growth in 1944	Ratio of Medical Plan Members to Blue Cross Plan Members	Percentage of Area's Population Covered	Type of Arrangement
Oregon Physicians' Service and affiliated county bureaus	Oregon	1929	108,000	1	257.0[3]	9.2	A
County Medical Service Bureaus	Washington	1933	200,000[2]	1	330.0[3]	10.5	A
California Physicians' Service	California	1939	130,000	40,000	56.0[3]	1.6	A-B
Medical and Surgical Care	Utica, N. Y.	1939	30,277	8,384	29.6	5.0	C
Michigan Medical Service	Michigan	1940	763,755	160,100	61.6	14.3	B
Western New York Medical Plan	Buffalo	1940	37,920	17,831	10.2	3.4	C
Medical Service Association[4]	North Carolina	1940	30,624	30,000	60.8	1.9	C
Hospital Care Association[4]	North Carolina	1943[4]	33,236				D
Medical Service Association of Pennsylvania	Western Pennsylvania	1940	22,000[2]	13,263	3.0[2]	0.6[2]	B
Hospital Savings Association	North Carolina	1941	63,717	24,346	27.3	1.95	D
United Medical Service	New York City	1942	77,412	39,851	4.4	0.9	C
Massachusettts Medical Service	Massachusetts	1942	75,770	53,604	7.9	1.9	C
Colorado Medical Service	Colorado	1942	45,136	34,516	16.6	4.2	C
Medical-Surgical Plan of New Jersey	New Jersey	1942	31,213	15,198	4.8	0.8	B
Group Hospital Service	Delaware	1943	36,326	24,318	37.4	13.3	D
Surgical Care, Inc.	Kansas City	1943	27,636	21,382	24.9	4.1	C
New Hampshire Physician Service	New Hampshire	1944	2,000[2]	2,000	6	6	C
Huntington Hospital Service	Huntington, W. Va.	1944	2,000[2]	2,000	6	6	D
Nebraska Surgical Plan	Nebraska	1944	500[2]	500	6	6	C

1. Not known; probably less than 15,000.
2. Approximate.
3. The Blue Cross plan in Washington has 60,000 members, that in Oregon 42,000. These are different persons than those enrolled in the medical plans, and the same is true of part of the enrolment in the California Blue Cross Plans. Elsewhere the members of the medical and Blue Cross plans are the same persons and the other figures in this column show the percentage of Blue Cross members who are enrolled in the medical plan.
4. Both plans are administered by Hospital Care Association. Membership is gradually being transferred from Medical Service Association to Hospital Care Association.
5. There are two statewide Blue Cross plans in North Carolina. Their medical plans have enrolled 3.8 per cent of the state's population.
6. Plan but recently started.

COMPARISON OF THE FOUR RELATIONSHIPS

A. This relationship leads to competition and conflict. In Washington and Oregon the county medical societies have long had their medical service bureaus offering complete medical care, including hospitalization, to employed persons. The hospitals were dissatisfied with these plans because they had no share in their control and because little progress in providing hospital care on a prepayment basis to all the people of the state was being made. Accordingly they started Blue Cross plans. In Washington and Oregon the medical plans and the Blue Cross plans were (when visited in January 1945) competing with each other, although there were elements on both sides who recognized the drawbacks of this situation and were endeavoring to find a basis for cooperation.

In northern California, California Physicians' Service and the Blue Cross plans formerly cooperated. That cooperation broke down and competition ensued. California Physicians' Service developed its own hospitalization, and the two Blue Cross plans developed their own surgical indemnity plans.[3]

In short, arrangement A is thoroughly bad. The medical plan is forced in self defense to develop its own hospitalization insurance, and the hospital plan must offer surgical coverage. Hence the situation develops into two plans, one sponsored by the medical profession and the other by the hospitals, competing with each other. Competition is a good American institution in its place. However, these plans are really nonprofit community services. Prestige and public support are attracted to them because they are sponsored by the medical profession and the hospitals. When the plans compete with each other that prestige and

1. These relationships are discussed by Mr. Lester H. Perry in an article entitled The Coordination of Medical and Blue Cross Plans, THE JOURNAL, Feb. 10, 1945, p. 321. We have arrived at different conclusions from those set forth by Mr. Perry.

2. The numerous county medical societies plans in Washington are here considered as if they were one plan. Likewise Oregon Physicians' Service and its affiliated county bureaus are also considered as if they were one plan.

3. The Oakland Blue Cross plan has sold its surgical rider to 30,000 of its 96,000 members, and the Sacramento plan has sold its surgical rider to 10,000 of its 28,000 members.

public support is dissipated. Nothing could be more detrimental to the growth of voluntary plans than the present situation on the West Coast. The potential market for prepayment is enormous, but little headway can be made until the medical and hospital plans get together.

B. This is an advance over A because it at least brings the two plans together and avoids competition and strife. A disadvantage may be that the cord binding the two plans is tenuous and may break down, leading back to situation A.

When two plans cooperate, certain activities must be performed jointly or by one plan for the other. Enrolment, collection of subscription charges, maintenance of records showing subscriber eligibility for care, publicity and public relations are of this character. There must be joint use of certain office facilities. Certain activities can be performed by each plan for itself, notably approval of claims, payment of hospitals or physicians and maintenance of relations with hospitals or physicians. (Thus, in Michigan and New Jersey the Blue Cross plans handle enrolment, collection of subscription charges and maintenance of subscriber records for the medical plans. The latter approve medical claims, pay physicians and maintain relations with the profession. In southern California there is joint maintenance and joint control of the sales force. The Blue Cross plan maintains subscriber records for both plans.)

Furthermore there must be coordination of the two plans with respect to major policies. In order not to confuse the public and impede acceptance of the two plans, enrolment regulations must be similar, the provisions as to types of cases covered or not covered, waiting periods, and so on, must be alike. Any change in the rates or benefits of the one which renders it more or less attractive will affect the sales of the other which is coupled with it.

One difficulty with B is that, in effect, it sets up two masters in the same household. The director of the medical plan may have his ideas as to how enrolment should be conducted and on the choice of the man or men to do it. The two directors may have conflicting ideas on the best methods of keeping subscriber records, on publicity and public relations. Each director, in time, will tend to have his own ideas as to how the other plan should be run. If either plan is forced to raise rates or to cut benefits in order to make ends meet, this will slow down sales of the other, and the director of the other plan will have his own ideas on how the situation could have been avoided or should be handled. In short, the two plans are really joint undertakings. The public which pays its dues to one organization thinks of them as one and cannot be persuaded differently. The success of the one affects the success of the other. Yet there are two administrators, and this always makes for trouble.

There are also questions of prestige. If the hospital plan is well developed by the time the medical plan is offered, the two plans together will be sold as Blue Cross, and the medical plan and its director will not like this. If the Blue Cross does the selling for the medical plan, it is the Blue Cross representative who meets potential subscribers. His main loyalty is to that organization. This is true not only of the field men but of all Blue Cross employees who give some of their time to the medical plan. The hospital plan may be pushed, the medical plan considered an extra. The Blue Cross director has to sell a service concerning which he has no say.

The director of the medical plan meets with the board of directors of the medical plan, and the director of the hospital plan meets with his board. Neither board has first hand knowledge of the problems of the other plan with which it is coupled. Conflicts between the two boards on joint matters may not be easily resolved. Further, if friction between the two directors reaches the point where neither will give way to the other, then each board will tend to back up its own director.

An advantage of B is that responsibility for the success of the medical plan is concentrated on one person who gives it his whole time and attention. The medical plan may be a side line with the hospital plan director, but the medical plan director is there to see that its problems receive due consideration.

Arrangement B is the one possessed by the Michigan plan which has more members than the combined membership of all the other plans which are cooperating with Blue Cross. It has worked here owing in large measure to the personalities of the men involved. That Michigan Medical Service has so many members demonstrates not so much the superiority of B as that it was coupled with a Blue Cross plan which had a meteoric rise and that from the beginning the automobile industry with its great groups of employees demanded joint hospitalization and medical coverage. It is significant that many of those connected with Michigan Medical Service and Michigan Hospital Service believe that the two should be unified.

We think plan B is not likely to be successful in many instances. It is apt to succeed in spite of, not because of, its administrative soundness. It contains the seeds of trouble and is likely to go backward to A or forward to C.

C. C is an improvement over B. From the director down, there is one single administration. There is one head within the organization. The difficulties of C are that it is not the most convenient method of securing coordination between the boards of the two plans and that the director is in a sense serving two masters and may feel less responsibility to the one than to the other.

On many matters, as we have seen, there must be joint determination of policy between the two plans. What size groups should be enrolled? What percentage of participation within a group should be required? Should individuals be enrolled? On what basis? Should rural enrolment be undertaken? Should there be resort to advertising? What types of publicity should be undertaken? Should higher rates be charged to individuals who drop out of groups? The one board must agree to any change of rates or benefits desired by the other. On all these matters of joint policy or interest, the executive director must go back and forth between the two boards. One board decides on a certain matter. The other board considers and suggests a different solution. The first board must reconsider. It is a waste of time on the part of all concerned. Joint meetings of the two boards and interlocking of some of the personnel will help to cut down this waste.

Under arrangement C the executive director of the two plans is apt to feel that he is really the employee of one or the other. Under most existing plans with arrangement C the director draws all his compensation from the hospital plan. Under a few he receives an extra $1,000 or $2,000 from the medical plan. This

situation encourages the executive director to feel that his allegiance is wholly or mainly to the hospital plan, and, as in B, possibly to think of the medical plan as a side line.

The medical profession may think that C is preferable to D, one board for both plans, because under C it has full control of the medical plan. Actually this is illusory. Where so many matters are of concern to both plans, then in effect any decision of one board must be approved by the other. The board of one plan must assent to any major decision of the other plan board. This means that one board shares control with the other. The separation of the two boards simply makes it more difficult for joint decisions to be arrived at.

Under C the medical plan has a head but no body. An arrangement under which one plan entrusts its entire fortunes, all its administration, to another plan probably cannot long endure. We feel that the solution, when both groups are ready for it, is to go on to D.

One sees the difficulties of C in clearer perspective if one projects thought to the time when dentistry and nursing are offered on a prepayment basis. Will there be a dental board and a nursing board with the director of the hospital plan serving as executive for all? Obviously, merger is the answer.

D. Arrangement D seems the common sense arrangement when the two groups are ready for it. It is the one to which the plans probably will ultimately come. Under this arrangement the hospital plan, as such, ceases to exist; the medical plan, as such, ceases to exist. Instead there is a combined medical and hospital plan—a health service plan.

Under this arrangement there is one single corporation with one board and one director. There is complete coordination of medical and hospital prepayment because they are unified. One single organization gives maximum economy, single authority, maximum public acceptance and equal responsibility on the part of the plan's employees to all services which they render. The director of this one health plan would feel equal responsibility to both hospital and medical prepayment. The board of directors should have equal representation from the hospitals and the medical profession. For example, the Chapel Hill, N. C., plan has a board of twelve members, four elected by the state medical society, four by the state hospital association and four public representatives. It goes without saying that the name of organization should reflect its makeup and purpose. It should not be —— Hospital Service but —— Health Service.

The Blue Cross symbol should be retained because of its public acceptance, but any device within the cross should symbolize health service in general.

An important advantage of arrangement D is that it facilitates solution of the vexing problems of the inclusion of radiologic and pathologic services and of anesthesia and physical therapy, when performed by physicians, in hospital and medical service plans. These services are medical services, yet the charges for them often or usually appear on the hospital bill and are therefore thought by the public to be hospital services. Physicians in these specialties quite properly desire that these services shall be included in the medical rather than in the hospital plan. Yet until the medical plan has as extensive a membership as the hospital plan the inclusion of these services in the medical plan and their exclusion from the hospital plan has the disadvantage for the subscribing public that a lesser portion of the hospital bill is covered. Furthermore, even if enrolment in both plans is coextensive, and the aforementioned services are offered under the medical plan, administratively it is simpler, where the charges for the mentioned services appear on the hospital bill, for the hospital plan to pay the full hospital bill and to debit the medical plan for its expenses on behalf of these services, rather than for one organization to pay part of the bill and the other organization to pay the other part. All of these difficulties are avoided if Blue Cross and medical plans are transmuted into a joint hospital and medical plan—a health service plan—with a changed name and changed board of directors to give proportionate representation to the two groups.

There are several difficulties in the way of ready acceptance of arrangement D. One difficulty is that in some places neither the medical profession nor the hospitals are ready for it. They are too afraid of each other to get at such close quarters. (In discussing this proposal one hears the doctors say they are against it because the hospitals would control, and the hospitals say they are against it because the doctors would control.)

Another difficulty is that a single combined plan means, in effect, a single reserve to back up both hospital and medical contracts. In many places the hospitals would be unwilling to underwrite the medical contract and vice versa. The hospital plan may have substantial reserves and be on a sound and tested financial basis. Medical plans are as yet on more of an experimental basis and, until the medical plans are also on a sound and tested financial basis and have some reserves, unification may not be desired.

A third difficulty is that the laws of a number of states say that medical and hospital prepayment must be provided by separate corporations. It would seem, however, that legislatures would in most states be responsive to recommendations of the medical profession and the hospitals and that laws could be changed. It is also possible in some instances to have two corporations but have the same board members on each.

A fourth difficulty is that the central organization of Blue Cross plans, the Hospital Service Plan Commission, was developed through and is affiliated solely with the American Hospital Association. If local Blue Cross plans are to be transmuted into joint medical and hospital plans, it is essential that the central organization of the plans should undergo the same transformation.

These difficulties can be easily removed if both the medical profession and the hospitals make up their minds to do so and face realistically the problems involved in the successful development of prepayment plans. Until these difficulties are removed, arrangement C is probably preferable.

CONCLUSIONS

Cooperation between medical and hospital plans is essential. This cooperation can be achieved under various arrangements, any one of which can function at least temporarily with success, depending on the stage of thinking of those who do the cooperating. Complete unification of hospital and medical plans into Blue Cross Health Service Plans seems to provide the final and best solution. It represents the end of the road. But less forthright arrangements may not be without their temporary value.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

At the October 1943 meeting of the Council it was decided that reports should be made on (1) the status of prophylaxis by Hemophilus pertussis vaccine and (2) the status of passive immunization with human hyperimmune pertussis serum. A report on the current status of prophylaxis by Hemophilus Pertussis Vaccine appeared in THE JOURNAL, *Sept. 30, 1944, page 294. The following statement on the Status of Passive Immunization and Treatment by the Use of Human Hyperimmune Pertussis Serum has been adopted by the Council for publication.*

AUSTIN SMITH, M.D., *Secretary.*

THE STATUS OF PASSIVE IMMUNIZATION AND TREATMENT IN PERTUSSIS

BY THE USE OF HUMAN HYPERIMMUNE SERUM

HARRIET M. FELTON, M.D.
PHILADELPHIA

Severe whooping cough in infants is one of the medical conditions before which the physician of today often feels completely inadequate. The incidence of this disease has dropped significantly during the past five years, but the mortality rate in children under 1 year of age continues to be very high. The statistics have been difficult to evaluate because many cases have not been reported, and in infants death is frequently caused by the complications of the disease rather than the actual disease itself. It has been estimated that about 25 per cent of the infants under 6 months of age who contract whooping cough succumb.[1] Active immunization cannot be applied directly to this highly susceptible group, since it is felt that the mechanisms for producing active immunity are not mature. It is obvious, therefore, that any specific method of prevention or treatment of whooping cough in this younger age group must consist of the administration of serum containing specific antibodies in large enough doses to combat existing infection.

The development and use of human hyperimmune pertussis serum has followed attempts at passive immunization and treatment by the use of whole blood, normal serum and convalescent serum, which have been tried with no particular success for a number of years.[2] A review of the literature covering this subject by Bradford[3] in 1935 concluded that the use of convalescent serum modified the disease if given before catarrhal symptoms appeared but was of doubtful aid when administered after the disease had become well established.

Jundell[4] in 1933 was the first to report the use of serum resulting from the inoculation of human beings with pertussis vaccine. Each of 5 whooping cough patients was treated with serum from one parent who had been immunized with pertussis vaccine. The immunization was begun as soon as exposure was discovered and consisted of two to three intramuscular injections at intervals of five to six days. The serum was collected on the fifth day after the second or third injection and was administered in three to four doses of 60 to 80 cc. every two to five days. This series was very small, but it was felt that the serum had been of some value.

In 1936 Kendrick[5] reported the preparation and use of "reinforced convalescent or hyperimmune" human serum in the prophylaxis of exposed infants. Adult donors with positive childhood histories of whooping cough were given a series of injections totaling 7 to 20 cc. of a suspension of 10 billion Hemophilus pertussis organisms per cubic centimeter. Each serum was positive for agglutinins and gave a very strong opsonic reaction. Serum was used in 10 to 20 cc. doses, given as soon as possible after exposure and, in addition, another dose of 10 cc. some days later. Of 11 infants injected before the onset of symptoms 9 escaped the disease, but it was felt that treatment in 6 cases after the onset of symptoms was not of benefit.

In 1937 McGuinness, Stokes and Mudd[6] reported the first results of the use of lyophiled hyperimmune whooping cough serum. This serum was used for prophylaxis in 12 children and for treatment in 15 others. Adult donors with a history of whooping cough in childhood were used. The donors were given one course of Sauer type vaccine every four months and were bled at the end of the first four months and at varying times thereafter. The serum was separated from the whole blood, rapidly frozen for storage, pooled, frozen and dried. After the first year of production of this serum the immunization schedule was changed to give three courses of three weekly injections totaling 90 billion organisms at four month intervals and to obtain serum samples at approximately one month after the third course. Agglutination titers were determined and, if found to be 1:1,280 or over, the donors were eligible for the serum pools. The results of this first small series suggested that this type of serum was of definite value in prophylaxis. It was felt that the number of treated patients was so small that the therapeutic effect could not be determined.

Katsampes, McGuinness and Bradford[7] in 1939 reported improvement in 18 of 22 children who were treated with the same hyperimmune human serum. Fifteen of these children were under 6 months of age. There were no deaths in this series of cases.

In 1939 Cohen and Lapin[8] produced a hyperimmune serum by giving donors 20 cc. of either Sauer's or Mishulow's vaccine over a six to eight week period. Serum was collected one or two weeks later. Following prophylactic use of this serum in 10 cc. doses for infants and 20 cc. doses for older children, 8 of 12 exposed infants, or 67 per cent, escaped the disease. At the same time following doses of at least 15 cc. for infants and 40 cc. for older children of convalescent

serum 28 of 33 (85 per cent) exposed children escaped pertussis. It will be noted that a larger dose of convalescent than of hyperimmune serum was used.

Cohen, Weichsel and Lapin [9] in 1940 used hyperimmune and convalescent serum in doses of 5 to 40 cc. in treatment. The former was used in 12 cases and the latter in 36 cases. About 50 per cent of the patients were under 1 year of age. The authors concluded that, if given early enough and in large enough doses, hyperimmune serum could be of benefit in some cases and that striking results could be obtained in others. These workers felt that this serum was of definite value in severe cases. The donors for this serum had received 170 to 200 billion organisms over a six week period and were bled two weeks after the last injection.

McGuinness, Bradford and Armstrong [10] in 1940 found that when lyophiled hyperimmune human serum was used in doses of 10 cc. for the average child and 20 cc. for the very young and intimately exposed children, and if given before the catarrhal stage, 78.3 per cent of 65 exposed children escaped the disease. Of the 18 cases in which whooping cough developed in this group, 13.3 per cent were very mild, 4.8 per cent were mild and 3.7 per cent were moderate. At this time a study of the use of this serum for treatment in a group of 100 cases was reported. The total dosage was from 40 to 50 cc. given in two or three doses at two day intervals. The results were recorded as excellent 32, good 31, moderate 20, questionable 14 and deaths 3. The deaths all occurred in infants under 2 months of age with severe bronchopneumonia, and not 1 of these infants had received a full dose of serum. Attention was called to the fact that the expected mortality rate for the age group under 6 months is 25 per cent. Fifty-one of the 100 cases were in this age group. It was observed in this series that the best results were obtained when the therapy was begun in the first two weeks of the disease.

Flosdorf, McGuinness, Kimball and Armstrong [11] in 1941 discussed the methods of preparation and assay of hyperimmune human serum. A comparative study of two schedules of immunization in the production of serum of high agglutinative titer was made. One group of donors was given a standard series of a total of 7 cc. of Sauer's single strength vaccine (10 billion organisms per cubic centimeter) over a period of three weeks. This was repeated at three to four month intervals for three or four times. A second group was given the standard series and then monthly injections of 2 cc. of vaccine. Titrations for agglutinins were made at the end of one or two weeks after the initial course of vaccine in each group, and donors whose serum titer was not as high as 1:1,000 or 1:1,500 were rejected. Bleedings of 200 to 400 cc. of blood were made at monthly intervals and the titers determined. It was recommended that the final titer of the pools be 1:1,280 or preferably 1:2,560. It was found that the second schedule was not only just as effective in raising the agglutinin titer but that there was less variation in the titers of this group when followed over a period of a year. Therefore this procedure appeared to be preferable.

Frank, Patton and Hamilton [12] in 1942 reported a mortality rate of 20 per cent in a series of 30 consecutive cases of whooping cough with bronchopneumonia treated with hyperimmune serum. No statement of the method of preparation or agglutinative titer of this serum was made. These authors reported a mortality rate of only 4 per cent in 77 consecutive cases treated with sulfathiazole. The conclusions drawn were that the serum had no specific effect but was "good supportive therapy." The doses of serum given in this study were below the minimum doses recommended by McGuinness.

In 1944 McGuinness, Armstrong and Felton [13] presented the results of further studies in prophylaxis and treatment by the use of lyophiled hyperimmune human pertussis serum. A change in the immunization schedule was reported. Since 1942 the Philadelphia Serum Exchange has used intermediate strength Sauer vaccine (15 billion organisms per cubic centimeter) in four weekly injections with a total of 7 cc. One month after the first course a sample of the donor's serum is titrated for agglutinins and if a titer of 1:2,560 has been reached the donor is eligible for the serum pool. At monthly intervals the titer is determined and an injection of 2 cc. of vaccine is given. The average pools of serum obtained by this schedule of vaccination have a titer of 1:2,560, as compared to 1:1,280 previously obtained with the use of single strength vaccine and the original schedule of injections. The results of the use of this serum in 308 exposed susceptible infants and children showed that 78.6 per cent did not contract whooping cough. Of 137 children continuously exposed 67.9 per cent escaped, in contrast to the expected 10 to 20 per cent in unprotected children. In this series it was observed that the duration of exposure was a very important factor since 44 (66.6 per cent) of the cases developed after continuous intimate exposure, 19 (28.8 per cent) after short intimate exposure and 3 (4.5 per cent) after casual exposure. The importance of adequate dosage was stressed by the authors, who recommend the administration of two injections of 20 cc. each from three to five days apart for all children who are subject to continuous exposure. The serum was given either intramuscularly or intravenously. It was observed that the best results were obtained when the serum was given in the first two weeks after exposure. It has been suggested that children who are exposed for periods extending beyond three weeks after the second prophylactic dose of serum has been given should receive an additional dose to maintain the antibody level over this long period.

The aforementioned authors reported the use of lyophiled hyperimmune serum after the onset of paroxysms in 442 patients with whooping cough; 236 of the patients were under 1 year of age and 176 were in the first six months of life. The results were classified as follows: excellent or good results 70.2 per cent, moderate results 19.9 per cent, poor results 8.6 per cent, and deaths 1.3 per cent. These results are consistent with the previous report on the first 100 cases treated. The minimum dosage recommended for treatment of older children or severely ill infants at this time is three 20 cc. injections given forty-eight hours

apart. Occasionally a fourth dose may be required some time later. The intravenous route is suggested for all critically ill children, although most of the serum has been given intramuscularly. In severe cases several intravenous doses of from 50 to 100 cc. may be necessary. The total number of deaths in the group reported was six. These patients were all moribund and none of them received the minimum recommended dosage of serum. Five of the deaths were in the group under 6 months of age, making a fatality rate of 2.8 per cent for this group, as compared with the expected rate of 25 per cent in untreated infants. Fifty-five of the patients in the study were known to have bronchopneumonia. At the time treatment was begun, 39 of these patients were given the minimum dosage of serum and no sulfonamide therapy. There were no deaths, and 25, or 64 per cent of the cases had excellent or good results. The percentage of children showing little or no response was somewhat higher among the older children, since they received proportionately less serum than the smaller children.

Scheinblum and Bullowa [14] in 1944 reported results of the use of lyophiled hyperimmune pertussis serum in treatment of 23 critically ill patients at the Willard Parker Hospital; 52.1 per cent of the patients responded with good results, 13.3 per cent with questionable results, and in 8.6 per cent of the cases the serum was ineffectual. It was observed in this study also that the best results were obtained in the younger children. There were 12 infants between 1 and 3 months of age, 75 per cent of whom responded with good or moderate results, and there were no deaths. There were 2 moribund patients in the study, 1 receiving only 20 cc. of serum intramuscularly and the other 40 cc. of serum intravenously before death. It was observed that there were 2 patients treated as late as the eighth and ninth week of the disease who responded with good results. In 11 of the 23 patients pneumonia developed as a complication, and in these chemotherapy in the form of sulfadiazine was used in addition to serum, both prior to and simultaneously with the serum. It was found that, while the temperatures fell following chemotherapy, the general condition of the patient remained unchanged until serum was given.

COMMENT

Until very recently there has been no therapeutic measure which has been able to influence greatly the clinical course of whooping cough, particularly in young infants. The development of the specific serum which is now called hyperimmune serum has been under way for less than ten years. The observations made thus far have been on small groups and without untreated control cases. The efficiency of hyperimmune human serum has been indicated only by the dramatic reduction of the fatality rate, especially in infants in the first six months of life.

In the prevention and treatment of whooping cough, as in other infectious diseases, there is advantage in using human serum, if possible, rather than animal serum in order to avoid sensitivity, especially in known allergic individuals. Human hyperimmune pertussis serum has not been observed to cause any severe local or general reaction. However, the preparation and use of immune rabbit serum has been tried by a number of investigators who feel that it may be used safely.

Bradford, Scherp and Brooks [15] used globulin fraction of antipertussis rabbit serum for prophylaxis in a group of 20 infants with familial exposure. Thirteen (65 per cent) were completely protected. Five of the 7 cases were mild and 2 were typical. One dose of 2 to 10 cc. of serum was used. It was stated that auxiliary tests of the serum seemed to indicate that the protective action was chiefly antibacterial rather than antitoxic. Bradford, Brooks and Katsampes [16] found either immune rabbit globulin, pertussis antitoxin or sulfadiazine alone to protect mice against experimental murine pertussis. However, they did not always obtain reproducible results, as was the case when sulfadiazine was combined with either of the two rabbit serums.

Some workers feel that the toxin is more important in pertussis infection than has been generally recognized and that therefore antitoxin should be used in prophylaxis and treatment. Strean, Lapointe and Dechene [17] and Lapointe and Strean [18] reported the use of rabbit antiendotoxic or antiendotoxic plus antibacterial serum for passive immunity in contacts and in treatment of the disease. They found that the antiendotoxin alone inhibits the disease or produces an aborted attack in most cases but feel that use of the combined serum is preferable in order to stimulate phagocytosis as well as to neutralize the toxin. Bullowa and Alterman [19] found that rabbit antitoxin prevents the disease even in continuous exposure if given early enough but is of little value in established cases.

Evidence from certain laboratory experiments with hyperimmune human serum seems to indicate that the protective action is antibacterial, although a small amount of antitoxin has been demonstrated. This antitoxin is probably the result of intensive repeated immunization with whole bacterial vaccine which has been shown to contain minute amounts of toxin.

The dosage schedule recommended for the hyperimmune serum was first made arbitrarily. It is now felt that in severe cases larger doses of serum than originally recommended should be used and that the intravenous route should be employed whenever possible. The importance of an additional dose of serum for prophylaxis in cases under long term exposure is stressed. The use of lyophiled serum facilitates administration and also insures against decreased antibody content on storage.

The National Institute of Health has authorized the preparation and distribution of hyperimmune pertussis serum. This agency recognizes no standard method of assay at this time. For three years the serum produced at the Philadelphia Serum Exchange has been tested by the agglutination technic described by Flosdorf, McGuinness, Kimball and Armstrong.[11] Hyperimmune pertussis serum also has been prepared by several other human serum centers in this country.

The studies reviewed in the paper indicate that in treatment it is possible to lower the mortality rate of whooping cough decidedly by the use of hyperimmune human pertussis serum given in adequate amounts. Significant passive protection has been obtained when the recommended dosage has been used.

REPORT OF THE COUNCIL

The Council has authorized publication of the following statement. AUSTIN SMITH, M.D., *Secretary.*

ANNUAL MEETING OF THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry of the American Medical Association convened at the Association headquarters, Oct. 13, 1944. Those in attendance were Drs. David P. Barr, H. N. Cole, Morris Fishbein, E. M. K. Geiling, Eugene M. Landis, James P. Leake, Stuart Mudd, E. M. Nelson, W. W. Palmer (Vice Chairman), Elmer L. Sevringhaus, Torald Sollmann (Chairman), Austin Smith and W. Barry Wood Jr. In addition to members of the headquarters staff there were present Dr. E. E. Irons, Secretary of the A. M. A. Board of Trustees, Dr. J. J. Moore, Treasurer of the A. M. A., Dr. Donald A. Wallace, Secretary of the Council on Dental Therapeutics, and Dr. Walton Van Winkle Jr. of the Federal Security Agency, Food and Drug Administration.

The following is an abstracted report of some of the more important discussions and actions:

Stability and Labeling of Phenarsine Preparations.—The Council discussed the question of stability of oxophenarsine hydrochloride (Mapharsen) and dichlorophenarsine hydrochloride, as specimens of the former had been received at the Council office showing variation from normal color. The Council voted that all claims of companies that changes in color of oxophenarsine and dichlorophenarsine have no significance must be deleted. Moreover, there should be a definite warning on the ampul that the contents of all ampuls which on dissolving in distilled water appear yellow to grayish or black should be discarded. Products fused in the tube should never be used. The Council also voted that all containers of individual ampuls should be dated in numerals of at least 8 point size in order to obviate difficulty in ascertaining their age; that informational material put out by the companies should stress the absolute necessity of keeping the compounds in the refrigerator, preferably at 0 to 5 C., and emphasize the necessity of using the earlier batches placed in the refrigerator, not the last ones.

Establishment of a Therapeutic Trials Committee.—The Council usually has considered drugs only after the evidence has been accumulated; it has not initiated clinical trials on substances fresh from the laboratory. However, it has watched and its members have participated in the activities of the Office of Scientific Research and Development and the National Research Council. It believes that the plan of cooperative clinical research which has been instituted during this war is valuable. It also believes that the British Therapeutic Trials Committee has proved its usefulness. Finally the Council believes that it should use its facilities and contacts toward furthering such work if it is necessary to supplement the work of the O. S. R. D. A committee known as the Therapeutic Trials Committee was formed to consider the project and to report to the Board of Trustees of the American Medical Association. This committee believes that the activities of such a group at the present time should take the form of mediating between manufacturers and clinics; that the work should be confined to new products of definite and outstanding promise on which adequate laboratory work is available; that the Committee should have full jurisdiction in the choice of products that it would sponsor; that the costs incurred in the actual trials should be the subject of contract between the manufacturer and the clinic conducting the trials.

Status of Thiouracil.—This drug, which has been the subject of considerable investigation in the medical control of hyperthyroidism, was considered and its status reviewed. It is not available at this time for general use.

Proprietary Names.—The question of accepting proprietary brands of drugs and of recognizing more than one proprietary name for one drug was reviewed. The Council voted that its procedure regarding names of products, which is explained in the official rules of the Council, should not be changed and that the Committee on Nomenclature should prepare a comprehensive and strong statement concerning the significance of names of products in relation to acceptance by the Council and the dangerous confusion that occurs when a single preparation is known under many names.

Principles of Cooperative Medical Advertising Bureau.—The operative principles of the Cooperative Medical Advertising Bureau were discussed and minor changes suggested.

Sale of Endocrine Preparations to the Public.—The Council discussed the sale of endocrine preparations, particularly cosmetics which contain estrogenic and other hormone substances. Such cosmetic preparations are frequently offered with claims that they will affect the physiology of the skin and bring about improvements in the texture and appearance of the skin. Some have stated that such drugs when used in small amounts cannot exert a local effect on the skin without having a general physiologic effect. Others have asserted that, if such preparations contain an adequate dosage to exert an effect on the human body, they may be dangerous; if they do not contain an adequate dosage, they are fraudulent. The Council voted to recommend that the referee review the subject and prepare a statement for publication.

Interpretation of "Nonofficial Constituents."—The Council voted to add the following statement to the paragraph on Nonofficial Constituents in Rule 1:

"Constituents that are not concerned in the pharmacologic action of the preparation need not be submitted in detail, but their nature and quantity must be disclosed to the Council so that it may be judged that they are inert. They must be declared on the label or package by such designations as will make their nature apparent."

Scope of Useful Drugs.—The scope of Useful Drugs was reviewed and it was decided that it should continue to be a book in which are described drugs that have a distinct and important field of usefulness not covered in a better manner by some other drug. It was also decided to include accepted proprietary names as synonyms.

Policy of Committee on Therapeutic Research.—The policies of the Council's Committee on Therapeutic Research were reviewed. The Council voted that the Chairman of the Committee on Therapeutic Research be authorized to ask for an increased annual budget.

Spanish and Portuguese Translations of N. N. R.—The Council has been requested to consider the issuance of Spanish and Portuguese translations of New and Nonofficial Remedies to be made available to the Latin American countries. The Council voted to explore the possibilities.

Digitalis and Purified Principles.—The Council voted that the dosage for purified digitalis principles in solid form should be stated by weight; in the case of injections, by weight and by U. S. P. unit equivalent; the Council further voted that it should acquire as soon as possible appropriate reference standards and that, when such standards are established, recommendations regarding declaration of dosage should be put into effect.

Nonproprietary Names.—The Council voted to request manufacturers to submit nonproprietary names for preparations which they offer under proprietary names, so that if a proprietary name is recognized there will be available at the same time, or soon after, a nonproprietary name in order to prevent the development and promotion of unsuitable nonproprietary names.

Advertising of Contraceptives to the Public.—The Council voted to adhere to its Rule 3 on the question of advertising of contraceptive products. Thus, such agents when advertised to the public are not eligible for consideration by the Council for inclusion in N. N. R.

Educational Activities.—The Council voted to continue its activities concerning projects of special interest to the general practitioner. At the same time it recommended preparation of a review of the status of oral vaccines for the prevention of "colds," this report to be published jointly with the Council on Industrial Health.

Advertising Brochures.—Because of the unnecessary length of many advertising brochures, the Council voted to prepare a statement for publication on the needlessness of such wastes of time and material.

Vitamins and Coenzymes and Sulfonamide Therapy.—The relation of vitamins and coenzymes to sulfonamide therapy was discussed; the Council will be especially alert to any developments in this field.

WAR AND INSECTICIDES

Shortly after our entry into the war, the need for means of control for a great majority of the medically important insects became imperative. The worldwide distribution of our troops and the crowding of civilian workers at home, together with the shortage of pyrethrum and rotenone, were aggravating factors. On the recommendation of the Committee on Medical Research, the Bureau of Entomology and Plant Quarantine initiated at Orlando, Florida, a series of experiments for the development of control methods to be used by the armed forces.

Three separate projects were organized: (1) body louse control, (2) repellents for mosquitoes and other flying and biting insects and for such parasites as mites, ticks and fleas, and (3) larvicides for the treatment of breeding places of Anopheles mosquitoes. On the basis of their early studies the Orlando investigators recommended a formula for the control of the body louse, the head louse and the crab louse consisting of 0.2 per cent of pyrethrins (using a 20 per cent pyrethrum concentrate), 2 per cent of N-isobutylundecyleneamide, 2 per cent of 2,4-dinitroanisole and 0.25 per cent of phenol S (antioxidant) in pyrophyllite. Details of the tests leading to the formulation of this powder and results of tests are discussed in a paper by Bushland and others.[1] This formula, designated as MYL, proved in comparative tests to be more effective against the body louse than other louse powders known to the investigators. It also proved effective in controlling the crab louse, Phthirus pubis (L.), and the head louse, Pediculus humanus humanus L. The repellents recommended are dimethyl phthalate, Rutgers 612 and indalone dimethyl phthalate. Dimethyl phthalate has been found effective against Aedes aegypti, chiggers and fleas.

A new synthetic organic product designated by the symbol DDT, which is derived from the generic name "dichlorodiphenyl-trichloroethane," in the meanwhile was being investigated for its insecticidal properties. Investigations made by Annand and his associates[2] of the Bureau of Entomology and Plant Quarantine have revealed that DDT powder is highly effective and longer lasting than any other lousicide in use. The powder is more effective than the MYL previously recommended by this bureau. The salient feature of DDT is its long lasting quality. It will provide almost complete protection against lice for three weeks and give effective control for a longer period. The most remarkable feature of DDT impregnated clothing is that the treatment kills lice even after the garments have been laundered several times.

A 5 per cent solution of DDT in crude kerosene was found to be the most satisfactory solution for the control of bedbugs, particularly under military conditions. The DDT was also found to be effective in the control of ticks, chiggers and house flies.

SURGERY IN THE RED ARMY MEDICAL CORPS

The American-British commission after its visit to the Soviet Union eighteen months ago commented that, on the whole, the Russian surgeons were abreast of the times. Our surgeons did not approve of everything they saw but felt that, as Sir Ernest Rock Carling put it, "the Russian soldier was safe in the hands of the Russian surgeons." During the first year of the present war the medical corps of the Soviet Union returned to the front lines 72 per cent of the wounded. By the end of the second year the number of wounded restored to active duty was 73.3 per cent. To this record is added the fact that the Red Army was entirely free from epidemic diseases.

Russia's authority on military medicine of the past century, Pirogov, stressed that good results in field surgery depend primarily on the correct solution of administrative and medical supply problems in the army and only secondarily on the quality of the medical work. On this precept the modern Russians built their system of military medical services. The effectiveness of the organization was stressed by the members of the Anglo-American mission and, in particular, by Loyal Davis,[1] who felt that we had much to learn from the Russians in this respect.

As pointed out by the surgeon general of the Russian army, Professor Smirnov,[2] the success has been possible because of a simple doctrine of war medicine under field conditions. This doctrine is based on the following principles: (*a*) a uniform conception of the origin,

1. Davis, Loyal: Organization of the Red Army Medical Corps, editorial, Surg., Gynec. & Obst. 79: 329 (Sept.) 1944.

2. Smirnov, Yefim: The Medical Corps in Red Army Operations: Its Tasks and Their Fulfilment, Brit. M. J. 1: 175 (Feb. 10) 1945.

development and progress of disease, and of the principles of surgical and therapeutic work in the field; (*b*) correct sequence in the treatment of sick and wounded at various stages during their evacuation; (*c*) the obligatory employment of brief, accurate and consistent medical documents, enabling the sick and wounded to be classified in a thorough manner and their treatment to be uniform at all stages of evacuation; (*d*) a single school of thought with uniformity in methods of prophylaxis and treatment of sick and wounded at the various stages of evacuation. The best results are obtained when wounds are treated within a few hours of their infliction. This fact, to a considerable extent, determines the organization and tactics of the medical corps in the field under various war conditions. The principle adopted is to bring the medical help to the wounded man rather than the wounded man to the doctor. Gunshot wounds are treated surgically as soon as possible; the army has organized field units in such a way that the wounded are removed from the battlefield even under enemy small arm and mortar fire and given skilled surgical treatment in the field medical units. The chief task of the forward medical units is to combat serious loss of blood and to give prophylactic treatment against infection of wounds. Another important principle is that of segregation of patients. Wounded who require specialized treatment for wounds of the skull, eyes, jaws, thorax, the long bones and the larger joints are cared for in all institutions, beginning with the mobile field hospitals operating in the zone of the army base. The treatment and evacuation of the slightly wounded and of medical cases are dealt with separately, beginning with the forward units. An important principle adopted by the medical corps is the treatment of wounded in stages of evacuation. At each stage the wounded are treated by specialists and are evacuated into the rear areas. Evacuation is not carried out mechanically from stage to stage but depends on the type of wound and the condition of the wounded and also on conditions at the front. Treatment given at the stages of evacuation is consistent and consecutive, progressing in scope and method as the distance from the forward medical station increases. Smirnov stresses particularly that the scope and methods of treatment, the organization and the speed of evacuation are determined more by the military situation than by purely medical considerations.

Success or failure of this system of treatment and evacuation, according to Smirnov, depends on the correct diagnosis of wounds and the proper classification of wounded, on the presence of a network of specialist hospitals, on precision work on the part of transport and the organization of clearing centers which insure the rapid dispatch of wounded to the next stage, and lastly on the maneuvering of available hospitals, transport and reserves in accordance with changes in the military or medical situation.

The complete freedom of the Red Army from epidemic diseases has been achieved by the simultaneous and correlated activity of all units concerned and is due to the fact that antiepidemic measures among the troops are not carried out by individual specialists but by the medical corps as a whole.

The surgeon general of the Red Army says that the Red Army medical service "does not stand still." Short courses for medical personnel are arranged to improve their knowledge of special branches, and numerous conferences of surgeons, physicians, epidemiologists and workers in other specialties are held at which the experiences of the most progressive specialists and institutions are studied, summarized and popularized.

SENATE DEBATE ON ELLENDER BILL

The Ellender bill, which provides for an adequate supply of premedical and medical students, was published in full in THE JOURNAL March 10, 1945. In the course of the Senate debate on the continuation of the Selective Service Act this bill was presented on the floor of the Senate by Senator Allen J. Ellender of Louisiana on Tuesday, April 24. He stated: "Mr. President, I consider the amendment a must measure. I think that it is absolutely necessary that provision be made now so that our medical colleges throughout the country may obtain students and train them properly in medicine and dentistry." In support of the measure Senator Ellender cited pertinent figures and read a strong supporting statement from the War Manpower Commission.

Mr. Ellender was questioned as to the reason for the Senate Committee on Military Affairs not having acted on this bill in the two months since its introduction into the Senate and its referral to that committee. In reply he stated that this delay was occasioned by the failure of the War and Navy departments to file a statement on the bill with the committee.

Senator Lister Hill of the Committee on Military Affairs stated that failure to hold hearings was "not because the Senator from Louisiana has not been diligent in pursuing the matter. I happen to know that he has been very diligent, but only this morning a letter came from the Navy Department in regard to this subject. . . . I happen to know that the Navy Department is opposed to the amendment. It was only yesterday that a letter came from the War Department. The War Department is also opposed to the amendment."

Senator Hill continued "I am not chairman of the Committee on Military Affaiirs, but as one member of that committee I say to the Senator that if he will withdraw his amendment I shall do everything I can to have the committee give him an expeditious hearing, expeditious consideration and expeditious action on the bill. I do not know what the action will be but certainly it

would seem to me that with a bill of this nature, with the interested departments reporting against it, if the Senator really wants to have his bill passed he will have to get the weight of the committee behind it."

Senator Ellender then withdrew his request for immediate Senate consideration of the bill after the following promise had been made by Senator Edwin C. Johnson of Colorado: "As acting chairman of the Senate Committee on Military Affairs until the return from Europe of the Senator from Utah, Mr. Thomas, I may say that if I am still acting chairman next Tuesday and the Senator from Louisiana is ready to have his bill considered by the Senate Committee on Military Affairs next Tuesday it will be called up."

Since the War and Navy departments have now replied to the Committee on Military Affairs, it would appear that there is no further justification for delay of serious consideration of the measure. Such consideration, and perhaps even favorable action, may have been taken by the time this goes to press.

Current Comment

EDITORIALS FOR EDITORS

The National Physicians Committee has recently begun publication, in several of the periodicals devoted to the interests of the press and to the journalistic profession, of a series of announcements that present the point of view of the medical profession in relation to social security and medical care. The first of these advertisements, entitled "Guardians of a Priceless Heritage," emphasizes the importance of preserving the sanctity of the human personality and the subordination of the state in the maintenance of democracy. It points out that the placing of medical care under the federal government would not necessarily regiment the medical profession but would quite certainly regiment the public as far as medical care is concerned. The second announcement, entitled "Social Security," urges editors to interpret for the people the meaning of the laws relating to social security. This announcement emphasizes that payments are made in cash under the present benefits of the Social Security Act but that it is always proposed that medical care be supplied in the form of service. The final paragraph of this section reads:

> No sane person can believe that any bureaucrat can direct the rendering of medical care without actual suicidal deterioration in the quality and effectiveness of the service that is provided. It is the ultimate in absurdities. The people should be told the facts. Editors should tell them.

The third announcement, "The Sentinel on the Wall," tells editors that the people depend on them for warnings when danger nears. The theme is the place of the physician in the rendering of medical service. Quoting again in part:

> . . . the basic factor responsible for the unequaled effectiveness of the practicing physician is that the whole of his effort always is concentrated on treating and curing the patient—the human being who is sick. . . . Bureaucratic direction would destroy the intangible, indefinable essence that is the secret of the American doctor's effectiveness.

The National Physicians Committee has rendered an excellent service in the field of public relations for American medicine by the publication of this series of advertisements addressed to the editors of the American press.

RATIONING OF PRIVATE DUTY NURSES

Elsewhere in this issue (Medicine and the War, page 36) is a plan which has been adopted by the Rochester (N. Y.) Hospital Council to regulate the employment of private duty nurses in member hospitals. The plan is designed to limit the utilization of nursing personnel on the basis of actual physical need as determined by the attending physician and a reference committee of the medical staff in which the hospital administration is also represented. It further provides that the services of private duty nurses may be transferred or extended to the care of other patients as conditions may demand. Hospitals in every part of the country should consider the development of a similar program so as to conserve nursing personnel and make possible a wider and more equitable distribution of nursing service in civilian hospitals. Even more important, however, is the fact that a voluntary program of this type will help to release additional graduate nurses to meet the urgent demands of the armed forces. If all hospitals will carefully limit their nursing service to actual minimum needs, many of the 24,000 private duty nurses now employed in nonfederal hospitals will no doubt become available for general hospital duty or military service. While it is recognized that special nursing is often required, the patient's ability to pay should not be the determining factor in the assignment of private duty nurses. Under present conditions there can be no justification for luxury care.

ASHESHOV SUGGESTION IN TUBERCULOSIS

In *Science* for Feb. 2, 1945 appeared an article by Igor N. Asheshov and Frieda Strelitz entitled "An Antibiotic Substance Active Against Mycobacterium Tuberculosis." In this article the authors report experiments performed at the University of Western Ontario, London, Canada, with a fungus known as Aspergillus fumigatus. Crude preparations with substances derived from the growth of this fungus indicate, according to the authors, that:

> (1) they possess a high degree of activity against staphylococci, preventing their growth in 1:700,000 of the dry crude substance; (2) their bacteriostatic activity against BCG appears to be higher, preventing growth in at least 1:1,400,000 dilution; (3) their bactericidal action against BCG is equal to or slightly lower than their antistaphylococci activity. . . . The active substance investigated may be similar to fumigacin or helvolic acid (Waksman [Waksman, S. A.: *Science* 99:220, 1944]; Chain et al. [Chain, E., et al.: *Brit. J. Exper. Path.* 24:108, 1943]), though some of its properties seem to indicate that the two antibiotics are not identical. Some other, as yet unidentified, molds were found to produce active substances against tubercle bacilli and are now under investigation.

Certainly this work is hardly sufficiently advanced even to suggest that any of these substances are effective in the treatment of tuberculosis in human beings. The experimentation would seem to be in an exceedingly early stage. Unfortunately the columnist Ed Sullivan, in his syndicated column not long ago, made this statement:

> To tuberculosis patients: Contact American Medical Journal on Dr. Asheshov's Western Ontario U. experiments.

The result has been a flood of letters addressed to the headquarters office of the American Medical Association by people who think that a remedy has been found. It is unfortunate that so many people will have to be told that the experiments of Asheshov are only indicative and that there is nothing that is immediately useful from them.

THE EVALUATION OF RESULTS IN THE TREATMENT OF INFANTILE PARALYSIS

Elsewhere in this issue of THE JOURNAL (page 21) appears a statement by a special committee appointed by the Scientific Advisory Board of the National Foundation for Infantile Paralysis to determine standards for the evaluation of the results of treatment of infantile paralysis. The committee emphasizes, and rightly, that the evaluation of various forms of treatment is of the utmost importance in determining the procedures to be recommended when an epidemic strikes. Already it is well established that the amount of damage done to the nervous system primarily and to the muscles secondarily in this disease varies from one epidemic to another. Certainly mortality rates vary in different epidemics. Even the portions of the body that are primarily affected seem to differ; respiratory paralysis is much more frequent during some outbreaks than during others. The ultimate damage seems to vary according to the methods of treatment followed, yet assessment of both the immediate and the ultimate disability is exceedingly difficult. The committee has indicated research which might be undertaken to determine uniform methods of evaluation.

PEPTIC ULCER MORTALITY IN BRITAIN

According to mortality studies based on the reports of the Register General for England and Wales [1] peptic ulcer ranks low as a cause of death. In the ten year period preceding the war, however, the mortality among men increased steadily; since the outbreak of the war this increase has been accelerated. A comparison of mortality rates for the years 1911-1920 and 1932-1934 shows that the mortality rate in men after age 35 has increased, the rise becoming greater with advancing years, so that mortality from peptic ulcer at ages 45-75 has almost doubled. With women the trend has been different, with a decline at all ages under 55 and a relatively small rise from ages 55-75. Indeed, this significant rise in ulcer mortality for man at 45-65 has contributed to the lack of improvement in the death rate from all diseases for men of these ages, whereas in women there has been a steady decline. Mortality in men from gastric and duodenal ulcer varies widely in different social classes. Up to age 55 mortality from gastric ulcer in men rises in a regular manner with a descent in the social scale. There are five times more deaths in the poorest class at ages 25-45 than in the wealthy and professional groups. But this is not true for duodenal ulcer. Up to age 55 there is little difference in mortality among social groups, but after age 65 duodenal ulcer mortality definitely increases in the wealthy and professional groups, so that at age 70 and over the duodenal ulcer mortality is more than two times greater in the wealthy than in the poor. In men between the ages of 35 and 70 the mortality rate is over 100 per cent higher in London than in the rural areas. The acute depression of the 1930s with unemployment led to a reduction in ulcer mortality, but when unemployment declined mortality rose sharply. Almost immediately the war produced a rise in the mortality from peptic ulcer. Despite distortion due to population changes, it appeared that the rising mortality shifted with changes in air attacks from London to other parts of England and Wales. The pattern of mortality has remained consistent from year to year. This survey asks more questions than it answers, but it reflects the multiplicity of factors concerned in the pathogenesis of and mortality from peptic ulcer.

VOCATIONAL GUIDANCE PAMPHLETS

Two authoritative pamphlets on "The Outlook for Women in Occupations in the Medical Services" dealing with physical therapists and occupational therapists have just been published by the Women's Bureau of the U. S. Department of Labor.[1] The excellent material in both pamphlets is a source of information for those concerned with vocational guidance and is of inestimable value to all who plan to obtain training in these occupations. Prior to publication each pamphlet was reviewed by representatives of various agencies or organizations who are leaders in these fields. Emphasis has been placed on presenting a clear, concise picture of the scope of the occupation, employment before the war, changes that have occurred as a result of the war, earning power of these therapists, and future needs for workers who have had adequate training and experience. Additional pamphlets will be printed to present pertinent information on other occupations in the medical field. Some of these discussions of occupations will be printed separately because of the timeliness of this information, but the entire series will be published later together with a discussion of important "trends affecting the many women employed in these services so important to the nation whether at peace or at war." The series will be listed as required reading by vocational guidance counselors.

1. Published by the Women's Bureau of the United States Department of Labor, the pamphlets are available at 10 cents each by addressing the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. The writer should request Bulletin 203, numbers 1 and 2.

MEDICINE AND THE WAR

ARMY

CONSERVATION OF X-RAY FILM

Owing to the serious shortage of x-ray film for both military and civilian purposes, the Army Medical Department is making every effort consistent with the maintenance of high professional standards to conserve it, Major Gen. Norman T. Kirk, Surgeon General of the Army, recently announced.

The Army Medical Department has had a steadily increasing need for x-ray film as a result of the large number of battle casualties and the necessity of taking numerous x-ray pictures in connection with the treatment of these patients.

Detailed instructions have been issued to all army medical officers to conserve film. Although a medical case history will be prepared on every man involved in the redeployment of troops following VE day, chest x-rays will not be made of all because that was done prior to shipping the men overseas. Since that time the Army has kept a critical medical eye on the health of the troops for symptoms of tuberculosis or any other disease. However, if tuberculosis or any other chest disease is suspected, an x-ray examination will be made.

Prior to reassignment under the redeployment plans, whatever is necessary medically will be done to bring the men to the fullest possible point of physical and mental efficiency, General Kirk stated.

Largely as a result of the Medical Department's program of screening soldiers by chest x-rays on induction, the incidence of tuberculosis has been only one tenth as high in this war as it was in the last war.

Figures in other fields of medicine reflect the benefits that the American soldier is deriving from the intensive efforts made to safeguard his health. The death rate from pneumonia has been reduced from 24 per cent in the last war to 0.6 per cent in this war. The incidence of malaria is only one fourth what it was in the early stages of this war.

These standards of low disease incidence must be maintained or improved if possible, General Kirk pointed out, but every reasonable economy must be used to stretch out the critical supply of x-ray film for both military and civilian use.

SERVICE COMMAND CONSULTANTS IN MEDICINE TRANSFERRED

Col. Vern R. Mason, former consultant in medicine of the Ninth Service Command, is now on duty overseas as medical consultant of the Pacific Ocean Area.

Col. Irving S. Wright, former consultant in medicine, Sixth Service Command, is now consultant in medicine, Ninth Service Command; Col. Alexander Marble, former chief of medical service, Harmon General Hospital, is now medical consultant, Sixth Service Command, and Lieut. Col. Worth B. Daniels is now chief of medical service at Harmon General Hospital, Longview, Texas.

GENERAL ROGERS HONORED BY TWO ALLIES

Brig. Gen. John A. Rogers, surgeon of the First Army, was recently awarded the medal of Officer, Order of the British Empire, and the French Croix de Guerre with Palm in recognition of his contribution to the Allied victories on the western front.

DR. GEORGE E. BURCH APPOINTED CONSULTANT

Dr. George E. Burch, associate professor of experimental medicine, Tulane University of Louisiana School of Medicine, New Orleans, was recently appointed civilian consultant to the Surgeon General for diseases of peripheral blood vessels with particular emphasis on trench foot and allied conditions.

EDUCATIONAL OPPORTUNITIES FOR ARMY DOCTORS

Major Gen. George F. Lull, Deputy Surgeon General, recently reported that since the start of World War II over 6,000 selected medical officers have been graduated from short but intensive courses given by the Medical Department in some thirty critical medical and surgical specialties. In addition, refresher courses in general medicine and surgery provide medical officers with a chance to "brush up" before returning to professional assignments after other duty.

Many doctors also benefit while in service from working under key professional personnel in military hospitals. Other medical officers who have been on duty with combat troops in the field are given an opportunity to brush up on their specialty through the rotation policy.

General Lull reported that 350 doctors have been reassigned from field to hospital duty during the past year in the Mediterranean theater and "the merit of intratheater rotational plans has been pointed out to other theaters and is being encouraged in order that the maximum number of doctors might receive refresher training while they are still in military service."

In the postwar period, General Lull added, all doctors will be entitled to professional training, after their release from service, under the G. I. Bill of Rights, and those who remain in the Army will have the opportunity for refresher training at selected military hospitals and civilian schools.

ARMY X-RAY CONFERENCE

A three day conference was recently held at the Medical Department Equipment Laboratory, Carlisle, Pa., attended by representatives of the Army Service Forces, Army Ground Forces, Army Air Forces and U. S. Navy, together with representatives of industrial companies manufacturing x-ray equipment. Improvements in present x-ray equipment and requirements for future development were discussed. Captured German x-ray equipment also was demonstrated at the conference.

NURSES INTERVIEWED

The American Red Cross is conducting personal interviews with all nurses classified as "available" by the Procurement and Assignment Service. Physicians, hospitals and hospital boards, industries, health agencies and registries which have contact with "available" nurses should be urged to give opportunity to the interviewers from the Red Cross to consult with these nurses, since this is essential for recruitment.

NEW CONSULTANT IN DERMATOLOGY

Major Clarence S. Livingood was recently appointed consultant in dermatology to the Surgeon General. Major Livingood recently returned from overseas, where he had been stationed at a general hospital in the India-Burma Theater since 1942. While there he received the Legion of Merit for outstanding work in dermatology.

COLONEL COOK DIRECTOR OF OCCUPATIONAL HEALTH DIVISION

Lieut. Col. William L. Cook Jr. was recently assigned director of the Occupational Health Division, Preventive Medicine Service, Office of the Surgeon General, succeeding Col. Anthony J. Lanza, recently retired from active duty. Dr. Cook graduated from Columbia University College of Physicians and Surgeons, New York, in 1934 and entered the service May 7, 1942.

ARMY AWARDS AND COMMENDATIONS

Brigadier General James E. Baylis

The Legion of Merit was recently awarded to Brig. Gen. James E. Baylis, formerly of Cincinnati. The citation accompanying the award stated that "as surgeon of the Fourth Corps Area from Oct. 1, 1940 to Jan. 24, 1942 his energy, sound judgment and foresight contributed materially to the expansion, supply and operation of the Corps Area Medical Service and the initiation of preventive sanitary methods for reducing the sick rate. He planned and supervised the efficient evacuation of patients from the First and Third Army Maneuvers in 1941. As commanding general of the Medical Replacement Training Center, Camp Joseph T. Robinson, Arkansas, from Jan. 25, 1942 to Oct. 1, 1943 he organized and directed the activities of this installation with exceptional success, completing the training of more than 46,000 replacements. Utilizing the existing facilities provided, he transformed a standard military camp into the most important training installation in the Eighth Service Command. The detailed arrangements which he perfected for the field sanitation, administration and the motor and tactical training of his troops were unique in their effectiveness and attractiveness. He demonstrated unusual leadership and ingenuity in the development and application of training aids and expedients to provide shade and shelter for his troops during outdoor instruction. His work at this training center was a noteworthy contribution to the war effort." General Baylis graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1910 and has been in the service since May 28, 1912.

Colonel Alfred A. DeLorimier

Col. Alfred A. DeLorimier, formerly of Washington, D. C., was recently awarded the Legion of Merit for "service as director of the Department of Roentgenology, Army Medical School, Army Medical Center, Washington, D. C., from Sept. 8, 1939 to Oct. 1, 1942. He developed an easily transportable, complete and efficient field x-ray equipment for the Army which permits the location of bullets and shell fragments in the body of a wounded man and makes it possible for the surgeon to extract them. He tested all types of roentgenologic materials procured for the Army and formulated the specifications necessary for their purchase. He made extensive studies of the use of photoroentgenography and was instrumental in developing stereoroentgenography, which has a valuable use in induction centers and in mass surveys. By his initiative, original thinking and development work he has performed outstanding service and contributed materially to the war effort." Dr. DeLorimier graduated from the University of California Medical School, San Francisco, in 1927 and entered the service May 10, 1929.

Lieutenant Colonel George T. Colvard

Posthumous award of the Bronze Star Medal was recently made to Lieut. Col. George T. Colvard of Deming, N. M. The citation accompanying the award mentioned "service from Aug. 29 to Sept. 7, 1944. He served as medical officer of a prisoner of war camp and aboard a prison ship, caring for hundreds of men. While aboard ship he taxed his strength to the limit of physical endurance in caring for the weak and sick. He never paused to rest while on the ship as the men in the stifling hold often became unconscious as the result of the severe heat and lack of oxygen but ministered to them at the sacrifice of his own health. Colonel Colvard, who lost his life while serving his fellow men, demonstrated unremitting effort and devotion to duty." Dr. Colvard was reported killed in action Sept. 7, 1944 in the sinking of a Japanese prison ship off the Philippine Islands. He graduated from the Medical College of Virginia, Richmond, in 1924 and entered the service Jan. 6, 1941.

Major William E. Clark

Major William E. Clark, formerly of Mason, Mich., has been awarded the Bronze Star "for meritorious service in connection with military operations against the enemy of the United States in France, Luxembourg and Belgium during the period from Oct. 13, 1944 to Feb. 15, 1945. As division neuropsychiatrist he treated large groups of patients, as many as 127 on one occasion during one day. Through his untiring efforts and his professional ability he was instrumental in returning to duty a large number of men who otherwise might have been lost to the division." Dr. Clark graduated from the University of Michigan Medical School, Ann Arbor, in 1936 and entered the service July 25, 1942.

Major Elmer A. Kleefield

The Bronze Star was recently awarded to Major Elmer A. Kleefield, formerly of Forest Hills, N. Y., "for meritorious service in connection with military operations against an enemy of the United States from July 4, 1944 to Jan. 24, 1945. As radiologist of the 34th Evacuation Hospital, Major Kleefield distinguished himself by his outstanding performance of duty. Exhibiting the highest professional attainments and zealous devotion to duty, the accomplishments of Major Kleefield distinguish him as an outstanding officer and merit high commendation." Dr. Kleefield graduated from Long Island College of Medicine, Brooklyn, in 1930 and entered the service Nov. 3, 1942.

Captain Stanley E. Morgan

Capt. Stanley E. Morgan, formerly of New Orleans, was recently awarded the Bronze Star. The citation accompanying the award explained that, "learning of several wounded soldiers badly in need of medical care, Captain Morgan braved heavy enemy mortar and small arms fire to reach the forward position in which they were. When enemy attacks forced other men of the position to withdraw, Captain Morgan supervised the evacuation of less seriously injured and elected to remain with those casualties who were too dangerously injured to be moved, despite the risk of capture or death." Dr. Morgan was taken prisoner by the Germans Oct. 6, 1944. He graduated from Louisiana State University School of Medicine, New Orleans, in 1941 and entered the service in May 1942.

Captain Lemuel Bowden

Capt. Lemuel Bowden, formerly of Norfolk, Va., was recently awarded the Legion of Merit for "services at Fogo Island, Newfoundland, from Nov. 3, 1943 to Nov. 24, 1944. As platoon surgeon of the 685th Signal Aircraft Warning Station, he gave freely of his technical skill and ability by rendering services to the civilians of Fogo Island at great personal sacrifice. In addition to his duties as platoon surgeon he performed many major surgical operations under adverse conditions with little equipment and at places far removed from his base." Dr. Bowden graduated from Harvard Medical School, Boston, in 1939 and entered the service Jan. 15, 1943.

Captain William A. Pallone

The Air Medal was recently awarded to Capt. William A. Pallone, formerly of Flushing, N. Y. A letter received from the Commander Officer by his family recently stated, in part, "It was an award made in recognition of courageous service to his combat organization. He was cited for meritorious achievement while participating in aerial flights in the Southwest Pacific Area from Aug. 12, 1943 to June 1, 1944. He took part in sustained operational flight missions during which hostile contact was probable and expected. These flights included bombing missions against enemy installations, shipping and supply bases and aided considerably in the recent successes in this theater." Dr. Pallone graduated from the Royal University of Rome in 1936 and entered the service Sept. 22, 1942.

Captain Richard J. Ackart

Capt. Richard J. Ackart, formerly of New York, was recently awarded the Bronze Star for outstanding bravery on the field of battle. A member of a medical detachment of the 38th Infantry Regiment of the 2d Infantry Division of the First Army, Dr. Ackart is now in Germany, where he was awarded the medal by Major Gen. Walter M. Robertson, commanding general of the division. With this award Dr. Ackart has also received the Oak Leaf Cluster to his Bronze Star and the second Oak Leaf Cluster. According to the citation which accompanied the second cluster, "Company E was

fighting on the eastern outskirts of town and suffering many casualties from machine gun and aimed small arms fire. While working around the aid station, several men came to the aid station and told Captain Ackart that litter bearers were needed very badly in E company's sector. It was impossible to send out any more litter bearers because they were all with the assault companies. Noting the lack of litter bearers, Captain Ackart and one of his enlisted personnel grabbed a litter and went to Company E's sector. He was immediately stopped by the company commander and was told not to go any farther forward as the enemy had that sector under intense machine gun fire. Disregarding this advice, Captain Ackart and his helper went forward, creeping and crawling to a point less than 100 yards from the enemy tank machine gun fire. It was at this point that one of the officers of the battalion was mortally wounded, but despite this murderous fire about him Captain Ackart and his aid man unnecessarily exposed themselves to this fire from the enemy in order to evacuate this officer. Alone these two men, with but a slim chance of getting back to safety themselves, loaded this officer on the litter and miraculously got him back to the rear. Such gallantry, heroism and utter disregard for his personal safety reflect extreme credit on Captain Ackart and the military service." Dr. Ackart graduated from the University of Rochester School of Medicine and Dentistry in 1942 and entered the service in August 1943.

Captain Harold P. Sortman

The Silver Star was recently awarded to Capt. Harold P. Sortman, formerly of Wilmington, Del., "for gallantry in action in the vicinity of Lup, Sicily, July 12, 1943. Captain Sortman, with complete disregard for intense enemy artillery fire, left a sheltered area position and entered an area under bombardment so that he might better aid the wounded and supervise their evacuation. His noble and unselfish action reduced suffering and saved the lives of a number of men." Dr. Sortman graduated from Jefferson Medical College of Philadelphia in 1936 and entered the service in June 1942.

Lieut. Col. Edwin S. Wallace

Lieut. Col. Edwin S. Wallace, formerly of Lexington, Mo., was recently awarded the Bronze Star "for meritorious service in connection with military operations against an enemy of the United States in France, Germany and Luxembourg during the period Nov. 1, 1944 to January 6, 1945. As commanding officer of a medical battalion Lieutenant Colonel Wallace distinguished himself through continuous long hours of arduous work. In spite of most adverse conditions he efficiently planned and executed the treatment and evacuation of the sick and wounded in close support of combat elements. Lieutenant Colonel Wallace's outstanding devotion to duty and display of technical skill resulted in the reduction of trench foot and other diseases to an absolute minimum, thereby contributing substantially to the successful combat operations of the 10th Armored Division during the period. His ceaseless energy and enthusiasm were an inspiration to his fellow officers and men and are in keeping with the high traditions of the armed forces of the United States." Dr. Wallace graduated from Washington University School of Medicine, St. Louis, in 1935 and entered the service in November 1940.

Major Ronald A. Bettle

The Bronze Star was recently awarded to Major Ronald A. Bettle, formerly of Hattiesburg, Miss., "for meritorious service in Germany during the period Nov. 1, 1944 to Feb. 15, 1945 in connection with military operations against the enemy. As surgeon for his unit, Major Bettle was responsible for medical attention of an exceptionally large group of administrative, technical and reinforcement personnel dispersed over a wide area. By his ingenuity he provided outstanding medical care for the troops and won high praise from all concerned. His initiative and technical knowledge reflect great credit on himself and the military service." Dr. Bettle graduated from the College of Medical Evangelists, Los Angeles, in 1940 and entered the service Feb. 26, 1941.

MISCELLANEOUS

RATION PLAN FOR PRIVATE DUTY NURSES ADOPTED

The following plan for the employment of private duty nurses in Rochester hospitals was recently approved by the Rochester Hospital Council and endorsed by the six member hospitals. Effective March 1, the plan is intended to apportion available private duty nursing service on the basis of physical need of the patient rather than ability to pay. The plan provides that:

1. No private duty nurse be employed in any member hospital of the Rochester Hospital Council unless the attending physician attests in writing the need for her services in each individual case.

2. When, in the opinion of a physician, the service of a private duty nurse is necessary, he shall apply to the nursing department for the employment of private duty nursing service. Such application shall state the diagnosis and the reason why the physician considers private duty nursing essential. Such application may be made by telephone but must be substantiated promptly in writing.

3. In order to insure a fair allotment of nursing service and to provide a fair and impartial review of requests for private duty nursing service, there shall be in each hospital a reference committee consisting of representatives of the medical staff and the administration which shall have final decision on all matters relating to the employment of private duty nursing service for the duration of the emergency. (At the Rochester General Hospital this committee includes Drs. C. S. Lakeman, C. B. F. Gibbs, C. G. Parnall and F. C. Sutton.)

4. When private duty nurses have been employed for special patients they may be transferred to the care of other patients whose need is more urgent by the nursing department subject to the review of the reference committee.

It is suggested that, whenever conditions warrant, the services of a private duty nurse shall be made available for more than one patient.

USE OF DDT FOR MOSQUITO CONTROL IN THE UNITED STATES

A Joint Statement of Policy by the U. S. Army and the U. S. Public Health Service

Successful use of the new insecticide DDT to combat insect borne disease among our troops overseas has brought sudden renown and notoriety to this potent war developed insect killer. Dramatic reports of its large scale use to control epidemics, and especially the spraying of DDT from aircraft, have fired public imagination and fostered the hasty conclusion that DDT is a complete solution to all of our insect borne disease problems. However, it must be remembered that DDT distributed over the countryside not only destroys malaria carrying mosquitoes but also may kill other insects, many of which are beneficial. Much still must be learned about the effect of DDT on the balance of nature important to agriculture and wild life before general outdoor application of DDT can be safely employed in this country. It may be necessary to ignore these considerations in war areas where the health of our fighting men is at stake, but in the United States such considerations cannot be neglected.

Extensive investigations are now being carried out by authorized agencies to determine the usefulness and possible hazards in the large scale dissemination of DDT. Until more information has been obtained from such investigations and until it has been evaluated by all interested parties, plans to employ DDT indiscriminately for outdoor area control of insect disease vectors in this country are not to be encouraged.

Since the beginning of mobilization the Army has carried on an extensive antimosquito campaign inside military reservations, and the U. S. Public Health Service has maintained a cooperative program for the control of malaria in adjacent extramilitary areas. This joint effort has successfully prevented malaria from becoming a problem to troops in this country. To meet the hazard of possible spread of malaria

by troops returning from overseas, the Army's program in military areas has been intensified and the program of the Public Health Service has been extended to include certain additional selected areas in the South, where risk of transmission is greatest. Representatives of the Army and the Public Health Service have given full consideration to ways in which this mosquito control program might be strengthened by employing DDT. The following joint policy has been agreed on pending acquisition of further knowledge concerning the large scale outdoor application of DDT:

1. DDT will be used for residual spray application to houses and other buildings for the purpose of killing adult mosquitoes before they have opportunity to transmit malaria. The long lasting killing effect of DDT as a residual spray provides a highly effective means to prevent the spread of the malarial parasite. This method of use is safe and economical and, moreover, is welcomed by the householder because it provides freedom from insect annoyance.

2. The use of DDT as a mosquito larvicide will be limited to experimental investigations and to situations in which DDT has definite advantage over other larvicides in saving materials and manpower, and presents no hazard to fish and other wild life.

3. Distribution of DDT from aircraft for large scale area control of mosquitoes in military and adjacent areas in the United States will be limited to projects conducted with due regard to the possible effects of DDT on beneficial insects and all forms of plant and animal life and in accordance with safeguards established by the Surgeons General of the Army and the U. S. Public Health Service.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Illinois

Gardiner General Hospital, Chicago: Types of Diabetes Mellitus and Their Treatment, Dr. Arthur R. Colwell, May 9; Some Fundamentals in Psychotherapy, Dr. David Slight, May 16; Wound Healing and Tendon Surgery, Drs. Hilger P. Jenkins and Alfred Rasmussen, May 23.

Station Hospital, Fort Sheridan: Peptic Ulcer, Gallbladder and Liver Diseases, Drs. Walter L. Palmer and Lester R. Dragstedt, May 17; Thrombosis, Thrombophlebitis and Anticoagulants in Less Common Peripheral Vascular Diseases, Drs. Geza de Takats and Armand J. Quick, May 24.

Vaughan General Hospital, Hines: Presentation of Allergy Cases, Capt. W. H. Horwitz, May 11; Heart Disease and Allied Conditions, Drs. Newell C. Gilbert and George K. Fenn, May 16; Presentation of Medical Cases, Major R. N. Tindall, May 18; Bone and Joint Infections, Drs. C. H. Hatcher and David Markson, May 23; Intestinal Parasites, Capt. J. M. MacMillan and Capt. Nathan Brooks, May 25.

U. S. Naval Hospital, Great Lakes: Tumors of the Chest, Dr. Willard Van Hazel, May 15.

Mayo General Hospital, Galesburg. Chest Diseases, Drs. Paul H. Holinger and Henry C. Sweany, May 18; Low Back Pain, Drs. Adrien Verbrugghen and Fremont A. Chandler, May 23.

Station Hospital, Camp Ellis, Lewistown: Arterial Vascular Disease; Traumatic Lesions, Lieut. Col. Ford K. Hick and Lieut. Col. John H. Gibbon, May 16; Repair of Bone in Fractures and Diseases, Dr. James R. Regan, May 23.

Regional Hospital, Chanute Field. Dermatologic Diseases, Drs. James H. Mitchell and Francis E. Senear, May 16; Burns and Plastic Surgery, Drs. Wayne B. Slaughter and Volney B. Hyslop, May 23.

Indiana

Billings General Hospital, Fort Benjamin Harrison: Malignancies in the Army Age Group: Medical X-Ray and Surgical Diagnosis and Treatment, Dr. Danely P. Slaughter, May 16; Endocrinology, Drs. Willard O. Thompson and Carl P. Huber, May 23.

Wakeman General Hospital, Camp Atterbury: Virus and Rickettsial Diseases; Medical and Neurologic Diseases and Treatment, Dr. Jonas E. Salk, May 16; Psychosomatic Medicine, Dr. David Slight, May 23.

Kentucky

Fort Knox General Hospital, Louisville: Surgical Relief of Involuntary Movement, Dr. Paul C. Bucy, May 16; Some Common Problems Encountered in the Diagnosis and Treatment of Infections in the Genitourinary System, Dr. Norris J. Heckel, May 16; Digestive Disorders, Dr. Walter L. Palmer, May 30; The Support of the Circulation in Surgery, Dr. Dallas B. Phemister, May 30.

Nichols General Hospital, Louisville: Surgery Relief of Involuntary Movement, Dr. Paul C. Bucy, May 17; Some Common Problems Encountered in the Diagnosis and Treatment of Infections in the Genitourinary System, May 17; Digestive Disorders, Dr. Walter L. Palmer, May 31; The Support of the Circulation in Surgery, Dr. Dallas B. Phemister, May 31.

Nebraska

A. A. F. Station Hospital, McCook Army Air Field: Clinical Pathologic Discussion of Liver Diseases, Drs. Esley J. Kirk and Charles P. Baker, May 15.

West Virginia

Newton D. Baker General Hospital, Martinsburg: Chemotherapy in War Wounds, Dr. Frank L. Meleney, May 28.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, April 21, page 1061)

COLORADO

Colorado Psychopathic Hospital, Denver. Capacity, 78; admissions, 800. Dr. Charles A. Rymer, Acting Director (2 fellowships—psychiatry, September 1).

LOUISIANA

North Louisiana Sanitarium, Shreveport. Capacity, 132; admissions, 4,260. Mrs. Will Samford, R.N., Superintendent (intern).

MARYLAND

Johns Hopkins Hospital, Baltimore. Capacity, 1,034; admissions, 18,214. Dr. Winford H. Smith, Director (interns—otolaryngology, radiology, July 1).

MASSACHUSETTS

St. Anne's Hospital, Fall River. Capacity, 141; admissions, 3,740. Sister Marie Stanislas, Superior (resident—mixed service, July 1).

NEW HAMPSHIRE

Elliot Hospital, Manchester. Capacity, 159; admissions, 2,834. Mrs. Elizabeth M. McKay, R.N., Superintendent (resident—mixed, disqualified for military service).

NEW YORK

Auburn City Hospital, Auburn. Capacity, 255; admissions, 6,198. Mr. Jerome F. Peck Jr., Acting Superintendent (resident—mixed, disqualified for military service).

Jamaica Hospital, Jamaica. Capacity, 227; admissions, 5,279. Mr. Francis C. Leupold, Superintendent (interns).

St. Agnes Hospital, White Plains. Capacity, 177; admissions, 2,695. Sister M. Madeline, R.N., Superintendent (interns).

TENNESSEE

Nashville General Hospital, Nashville. Capacity, 337; admissions, 6,586. Mr. T. F. Connally, Administrator (resident—pathology, October 1).

TEXAS

Methodist Hospital, Dallas. Capacity, 225; admissions, 8,193. Dr. C. W. Sensenbach, Medical Director (interns, July 1).

VIRGINIA

University of Virginia Hospital, Charlottesville. Capacity, 571; admissions, 11,181. Dr. Carlisle S. Lentz, Administrator (assistant resident; graduate student, dermatology and syphilology, June 15, disqualified for military service).

Riverside Hospital, Newport News. Capacity, 233; admissions, 5,382. Dr. H. H. Towler, Superintendent (3 residents—mixed service, June 1).

Grace Hospital, Richmond. Capacity, 100; admissions, 4,135. Mr. R. H. Thomas, Managing Director (resident—mixed service, July 1, disqualified for military service).

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

April 28, 1945.

Ask Removal of Venereal Disease as War Disability

Congress and state legislatures have been asked to modify the Starnes Veteran Preference Act of 1944 to exclude venereal diseases as a war service connected disability allowing war veterans preferences in civil service appointments. The National Civil Service League, in a resolution, holds that enactment of Public Law 439 of 1944 entitles war veterans suffering from venereal diseases contracted in service to disability allowance. It claims that this puts a premium on misconduct and that such disability would be on a par with that paid men who lose arms, legs or eyes. The league contends that section 2 of an act of May 17, 1926 provided an amendment which said that "venereal disease shall not be presumed to be due to misconduct if the person in service complies with Army or Navy regulations requiring . . . treatment for such disease." The Starnes act automatically gives a veteran with service connected disability 10 points in Civil Service examinations. Venereal disease was not specified and under regulations, it is said, could easily apply as a disability for benefits.

The Problem of Illegitimate Children of Service Wives

The adoption Bureau of the District of Columbia Board of Public Welfare reports moral and legal problems in handling placements of illegitimate children of service wives, conceived after their husbands went overseas. Director Nina Trevett reports that of the 50 babies placed in permanent homes in the Capital during the past year, nearly all were illegitimate children of army, navy and marine corps wives. Typical of the boom in child adoptions throughout the country, Miss Trevett reports that the bureau has a waiting list of 114 would-be foster parents. War conditions, she said, have forced the bureau to abandon its prewar regulation requiring three months' study and observation of a child before it is placed with foster parents. The bureau has, in cases, sanctioned placement direct from hospitals. Customary procedure requires a three month study of a child to determine its mental and physical well being and a six month probationary period with the foster parents.

Seven Medical Leaders Elected to Academy of Sciences

Among thirty-five distinguished scientific leaders representing twelve general fields of science who were elected to the National Academy of Sciences at the annual meeting here were seven men in the field of medical science. They include Dr. Robert R. Williams, chemical director of the Bell Telephone Laboratories, who was the first to synthesize vitamin B_1; Dr. Clarence C. Little, managing director of the American Society for Cancer Control; Dr. Alfred Blalock, professor of surgery at Johns Hopkins University, who is noted for his studies of shock and, more recently, for finding that myasthenia gravis can be successfully treated in some cases by removal of the thymus gland in the chest; Dr. John R. Paul, professor of preventive medicine at Yale University, a disease fighter who has done much work in recent years in tracing infantile paralysis epidemics to learn more about how this disease spreads; Dr. Homer W. Smith, director of the physiologic laboratory at New York University, noted for his research on high blood pressure and kidney function; Dr. William C. Stadie, professor of the department of research medicine, University of Pennsylvania, and Dr. James L. Gamble, pediatrician, of the Harvard Medical School. Present at the annual meeting were 117 of the 350 members. This is the first time in the history of the academy that thirty Americans, the yearly limit permitted by its charter, were elected in one year. Also elected were five foreign associate members, among them Dr. Paul Karrer, Swiss, who shared the Nobel chemistry prize in 1937, for working out the chemical formula for vitamin A.

Senate Approves Bill for Capital Hospital Center

The Senate has passed without opposition a bill sponsored by Senator Tydings, Democrat of Maryland, to create a postwar 1,500 bed hospital center in Washington. It now goes to the House for consideration. The bill would authorize the Federal Works Administration to acquire a site immediately on termination of the war and provide two thirds of the cost of erecting and equipping buildings. The other third of the cost, estimated at 20 or 30 million dollars, would be borne by existing District hospitals, which would participate in establishment, maintenance and operation of the center. Hospitals which have indicated their interest in cooperating in the project are Garfield, Emergency and Episcopal Eye, Ear and Throat. The Senate bill would permit these hospitals to allocate their share of costs on agreement to repay them over a period of twenty years at 2 per cent interest. The center would include a nurses' school and home, parking areas and special laboratories, and the 1,500 bed hospital would be equipped with operating rooms, laundries, x-ray machines, heating plant and other necessary equipment.

Wisconsin Alumni Group Fights to Validate Vitamin D Patents

The Supreme Court has been asked by the Wisconsin Alumni Research Foundation to review a lower court decision holding invalid three patents relating to the use of vitamin D in treating rickets. The foundation filed a petition for a writ of certiorari in its suit charging Vitamin Technologists, Inc., with infringement of its patents. The appeal was made after the Ninth Circuit Court of Appeals ruled in June 1943 that the foundation's patents were void as against the public interest and lacking in invention. The patents were granted on discoveries made by Dr. Harry Steenbock, Wisconsin University professor, on producing vitamin D in foods and medicine by exposing them to ultraviolet rays. The circuit court decision reversed a Southern California federal district court ruling of 1941 which had held the patents valid and ruled that the vitamin firm had infringed on them. The foundation contended in its appeal to the Supreme Court that it was being denied relief against an infringer for refusing in the past to license oleomargarine manufacturers under the patents. "The patents in suit do not claim anything broader than Dr. Steenbock's inventions," said the petition. "The claims in all three patents are properly commensurate with the basic discovery or invention on which Dr. Steenbock made and the various species thereof. The claims are definite and clearly define the scope of the three inventions, having regard to the breadth and nature of the primary inventions."

District Venereal Disease Measure Awaits Approval

Endorsed by the U. S. Public Health Service and the Justice Department, legislation to tighten control of venereal disease in the District of Columbia has been drafted and is before the Budget Bureau for approval. District Corporation Counsel Richmond B. Keech has informed House District Committee Chairman Randolph, Democrat of West Virginia, that the

measure would be submitted to Congress soon, if expected approval is given. Representative Randolph previously had pointed out that the District Social Hygiene Society felt that existing health measures were "too indefinite and ineffective" for vigorous enforcement of venereal disease control measures.

Nation Supports Cancer Control Month Program

An encouraging response in National Cancer Control month is reported here. To facilitate contributions, Postmaster General Frank C. Walker reports that America's 43,000 post offices will receive envelops enclosing contributions which are simply addressed "Cancer" and will transmit them to a central point in each state. "The Postal Service welcomes the opportunity to throw its unusual resources into the fighting against cancer," Mr. Walker said. "It is perhaps true that our service is more familiar to the average citizen than any other governmental agency. The national campaign for the control of cancer, which is now under way, looks to the dissemination of information about the early symptoms of cancer, clinics for diagnosis and other health facilities available for its control. The press, radio and all other mediums are generously focusing public attention on the campaign now being conducted by the American Cancer Society and telling the public the easy way to mail contributions: 'Simply address it to Cancer, care of your local post office'."

Propose That Bethesda Hospital Be Named After Roosevelt

Naming Navy's Hospital Center at Bethesda in honor of Franklin D. Roosevelt is proposed by Representative Flood, Democrat of Pennsylvania, who says "There could be no more fitting tribute to the late beloved President, in the District area, than to name as a memorial to him the magnificent medical center at Bethesda. A great humanitarian, keenly responsive to pain and suffering in others because of his great heart as well as his own affliction, the late President also cherished the Navy and its fighting ships and brave men and women."

Community Attack on Venereal Disease Problem Proposed

A united community attack on the problems of sexual promiscuity and venereal disease is advocated by the National Women's Advisory Committee on Social Protection, reports Federal Security Administrator Paul V. McNutt. The committee conferred here with the Social Protection Division, Office of Community War Service, of the Federal Security Administration.

Capital Notes

Restrictions on production and distribution of physical therapy equipment established in limitation order L-259 have been removed, the War Labor Board reports. Also restrictions on shipments of medical x-ray equipment for civilian purposes by manufacturers have been eliminated.

In its request to citizens in this 176th week of the war, the government asked graduate registered nurses not available for military service to apply for a job in a Veterans Administration hospital, where 2,000 nurses are needed by June 30.

Señorita Anramarina Colmenares, one of Venezuela's first woman doctors, lauded American women who are aiding the medical profession and hospitals as nurses' aides. She is here as a guest of the Pan American Sanitary Bureau.

Negro physicians of Washington held a five day seminar at Howard University College of Medicine on current medical developments. The seminar was sponsored by the District of Columbia Tuberculosis Association, the District Medico-Chirurgical Society, the Social Hygiene Society and Howard College of Medicine.

Bureau of Information

ONE THIRD OF COUNTIES COMPLETE REPORTS

Ten states have completed and returned summary sheets for all their counties. Sixteen states have submitted partial returns and twenty-two states have not yet returned any material to the Bureau. The Rhode Island and the District of Columbia societies, however, are conducting local surveys and have indicated that the requested information will be forwarded to the Bureau as soon as these are completed. Word has been received that the Illinois summary sheets will be sent in shortly. Oregon has not been included in the table, since the necessary forms were mailed there only recently.

A tabulation of returns from state and county medical societies as of April 25 is presented herewith.

Returns from State and County Medical Societies

State	Number of Counties	Number of Counties Reported	Counties Unreported
County Returns Complete			
Arkansas	75	75	0
Connecticut	8	8	0
Iowa	99	99	0
Kentucky	120	120	0
Nevada	17	17	0
[illegible]	31	31	0
[illegible]	53	53	0
[illegible]	88	88	0
Utah	29	29	0
Wisconsin	71	71	0
Partial County Returns			
Alabama	67	62	5
Colorado	63	19	44
Florida	67	15	52
Idaho	44	4	40
Indiana	92	53	39
[illegible]	64	32	32
[illegible]	14	8	6
[illegible]	83	31	52
Montana	56	37	19
New Hampshire	10	8	2
New Jersey	21	7	14
[illegible]	62	3	59
[illegible]	46	23	23
[illegible]	95	57	38
West Virginia	55	34	21
Wyoming	23	13	10
No Returns Received			
Arizona	14	0	14
California	58	0	58
Delaware	3	0	3
District of Columbia	1	0	1
Georgia	159	0	159
Illinois	102	0	102
Kansas	105	0	105
Maine	16	0	16
[illegible]	24	0	24
[illegible]	87	0	87
[illegible]	82	0	82
Missouri	115	0	115
Nebraska	93	0	93
North Carolina	100	0	100
[illegible]	77	0	77
[illegible]	67	0	67
[illegible]	5	0	5
South Dakota	69	0	69
Texas	254	0	254
Vermont	14	0	14
Virginia	100	0	100
Washington	39	0	39
Total	3,037	997	2,040

Inquiries from medical officers or veterans are being received by the Bureau with increasing frequency. In order to be able to supply the requested information it is essential that county summary sheets be completed and returned promptly. Already veterans have asked for information about states which have not sent in any county forms at all.

Coming Medical Meetings

New Hampshire Medical Society, Manchester, May 15. Dr. Carleton R. Metcalf, 5 S. State St., Concord, Secretary.

Rhode Island Medical Society, Providence, May 16-17. Dr. William P. Buffum, 122 Waterman Street, Providence 3, Secretary.

Official Notes

DOCTORS LOOK AHEAD

During the next four weeks Doctors Look Ahead will present the following programs:

May 5. Bewildered Parents; about children who have got their parents down; speaker, Dr. George K. Anderson, Secretary of the A. M. A. Council on Foods and Nutrition.

May 12. National Hospital Day, a program broadcast direct from the Dora De Lee Amphitheater at Chicago Lying-in Hospital, commemorating the fiftieth anniversary of that institution and looking ahead to enlarged service and research in this and similar institutions; speaker, President Robert Maynard Hutchins of the University of Chicago.

May 19. Look Sharp, a program looking toward better vision for the American people.

May 26. Unfinished Business, a program looking ahead to progress toward unsolved or partly solved problems of medicine; speaker, Dr. Morris Fishbein, Editor of THE JOURNAL and of *Hygeia*.

Doctors Look Ahead is heard on one hundred and twenty-three stations of the National Broadcasting Company network each Saturday at 4 p. m. Eastern War Time (3 p. m. Central War Time). Some stations may record the program and broadcast it at a time which suits their schedule better. Local newspaper radio announcements should be consulted.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Selective Training and Service Act

Senator Ellender, April 24, offered his bill to provide for the deferment of premedical and predental students, S. 637, as an amendment to another bill that was being considered by the Senate, H. R. 2625, to extend the Selective Training and Service Act of 1940. After receiving assurances, however, of an early consideration of S. 637 by the Senate Committee on Military Affairs, Senator Ellender withdrew his amendment. A hearing on the Ellender bill has been scheduled by the committee for May 1.

The bill to insure adequate nursing care for the armed forces, H. R. 2277, has been reported favorably to the Senate by the Committee on Military Affairs, with amendments. One amendment excludes from the bill a person who has volunteered for religious service at home or abroad or who is taking theological training in order to consecrate her life to religious service. Consideration of the bill by the Senate is scheduled for the week beginning April 30.

Medical and Dental Corps

Representative May, Kentucky, has introduced a bill, H. R. 3070, providing that for the duration of the wars in which the United States is presently engaged and for six months thereafter the Secretary of War may, in his discretion, dispense with any part of the examination for promotion in the Regular Army of officers of the Medical, Dental and Veterinary Corps except those relating to physical examination. This bill will merely extend the provisions of a law enacted by the Seventy-Sixth Congress beyond the terminal date set forth in that law, May 15, 1945.

Senator Johnson, Colorado, proposes by S. 916 to remove the limitation on the right to command of officers of the Dental Corps of the Army. At the present time the right to command of dental officers is limited to the Dental Corps.

Representative Rivers, South Carolina, proposes by H. R. 2584 to provide more efficient dental care for the personnel of the United States Navy by requiring the Bureau of Medicine and Surgery to be reorganized so as to effectuate a greater integrity of the dental service. The dental functions of the bureau, it is proposed, shall be defined and prescribed to the end that the Dental Division will study, plan and direct all matters coming within the cognizance of the division. It will be specifically authorized to establish professional standards and policies for dental practice, to conduct inspections and surveys for maintenance of such standards, to initiate and recommend action pertaining to complements, appointments, advancement, training, assignment and transfer of dental personnel, and to serve as the advisory agency for the bureau on all matters relating directly to dentistry.

Physically Handicapped Persons

Senator Kilgore, West Virginia, has introduced S. J. Res. 58, providing that the first week in October of each year shall be designated as National Employ the Physically Handicapped Week. The President will be authorized and directed to issue a suitable proclamation, and governors of states, mayors of cities and heads of other instrumentalities of government, leaders of industry, educational and religious groups, labor, veterans, women, farm, scientific and professional, and all other organizations and individuals will be invited to participate in the program to enlist public support for and interest in the employment of otherwise qualified but physically handicapped workers.

Representative Randolph, West Virginia, has introduced H. R. 3067 to amend An Act to Regulate and Improve the Civil Service of the United States, by providing that no person shall be discriminated against in any case because of his or her total or partial blindness in examination, appointment, reappointment, reinstatement, reemployment, promotion, transfer, retransfer, demotion, removal or retirement, unless normal eyesight is absolutely indispensable in the doing of the physical acts to be performed.

Industrial Health

The House Committee on Labor has recently received testimony from representatives of labor organizations on the bill introduced by Representative Norton, New Jersey, H. R. 525, proposing an appropriation of $5,000,000 annually to enable the United States Department of Labor to cooperate with state agencies administering labor laws in establishing and maintaining safe and proper working conditions in industry and in the preparation, promulgation and enforcement of regulations to control industrial health hazards. Early action by the committee on this bill is anticipated.

Veterans Administration

Three recently introduced bills propose to facilitate the receipt of hospital treatment and domiciliary care by former members of the armed forces at institutions nearest their places of residence: S. 755, introduced by Senator Cordon, Oregon, H. R. 2989, introduced by Representative Huber, Ohio, and H. R. 2921, introduced by Representative Stigler, Oklahoma.

In a bill introduced by Senator Morse, Oregon, S. 850, it is proposed that the education and training provided for by the G. I. Bill of Rights shall be made available to veterans on an equal basis without regard to their age.

Miscellaneous

H. R. 2965, introduced by Representative Anderson, California, would permit the inclusion of land occupied by Dibble General Hospital within the corporate limits of the city of Menlo Park, Calif.

The name of the National Naval Medical Center at Bethesda, Md., would be changed to the Franklin D. Roosevelt Naval Medical Center under a bill introduced by Representative Flood, Pennsylvania, H. R. 2986, which is pending in the House Committee on Naval Affairs.

STATE LEGISLATION

Florida

Bills Introduced.—S. 228 and H. 309 propose to establish a college of medicine and dentistry as a part of the University of Florida. H. 276, to amend the workmen's compensation act, proposes, among other things, to require an employer to furnish to an injured workman such medical, surgical or other attendance or remedial treatment or supplies for such period as the nature of the injury or the process of recovery may require. Under the present law, apparently, the total charge against the employer for such services and supplies may not exceed $1,000.

S. 179 proposes that the responsibility for the enforcement of the laws relating to public health and to the practice of medicine, chiropractic, naturopathy, nursing and midwifery shall rest on all law enforcement officers of the state and the counties thereof and on the state board of health acting through its duly appointed agents.

Michigan

Bills Introduced.—S. 362 and H. 423 propose a system of compulsory health insurance.

New Mexico

Bill Introduced.—S. 263 proposes to authorize the public health department to work in cooperation with the Surgeon General of the United States Public Health Service and other federal agencies in connection with the survey of hospital facilities and needs of the state.

Pennsylvania

Bill Introduced.—H. 1163, to amend the law providing compensation for workmen acquiring stated occupational diseases during the course of their employment, proposes to add to the list of compensable occupational diseases infection or inflammation of the person due to bacterial or parasitic agents in any occupation involving direct contact with handling thereof or exposure to such agents, poisoning by sulfuric, hydrochloric or hydrofluoric acid, and any and all occupational diseases.

COMPULSORY HEALTH INSURANCE

Bills Considered in State Legislatures Jan. 1-April 15, 1945. Prepared by the Bureau of Legal Medicine and Legislation, American Medical Association, Chicago, April 25, 1945

A.

Bills to Provide Medical, Nursing, Laboratory, Dental and Hospital Services

State	Bill Number	Contribution	Status as of April 15
California	A. 449 (CIO Bill)	Employer, 1.5 per cent of wages; employee, same	Held in committee; probably dead
California	A. 800, S. 500 (governor's bill)	Employer, 1.5 per cent of first $4,000 paid each worker; employee, same	Held in committee; probably dead
California	A. 1200 (California Med. Assn. bill).	Varies for both worker and employer according to contract concerned	Held in committee; probably dead
California	A. 1414, A. 2129 (so-called Social Insurance Act)	Employer, 1 per cent of wages; employee, 1 per cent of wages; state, 1 per cent of wages	In committee; no other action
California	A. 1525	Employer, 1.5 per cent of wages; employee, same	In committee; no other action
California	A. 2097	Employer, 1 per cent of wages; employee, 1 per cent of wages; state, 1 per cent of wages	In committee; no other action
California	A. 2157 (so-called Optional Health Insurance Act)	Employer, 1 per cent of wages; employee, 1 per cent of wages up to $4,000	In committee; no other action
Connecticut	H. 601	Employer, 1 per cent of payroll; employee, none; state, 1 per cent of payroll	In committee; no other action
Michigan	S. 362, H. 423	Employer, 2 per cent of wages; employee, apparently none	In committee; no other action
New Mexico	H. 275	Employer, 1.5 per cent of wages; employee 1.5 per cent of wages up to $4,000	Dead
New York	A. 97	Copy of bill not available	Dead
New York	A. 141	Employer, 1 per cent of payroll; state, same; employee, none	Dead
New York	A. 260	Employer, 1 per cent of payroll; state, same; employee, none	Dead
New York	S. 336	Copy of bill not available	Dead
New York	S. 476	Employer, 1 per cent of payroll; state, 1 per cent of payroll; employee, none	Dead
Wisconsin	S. 412	Employer, 2 per cent of wages; employee, 2 per cent of wages	In committee; no other action

B.

Bills to Provide Cash Payments for Sickness—So-Called Cash Sickness Insurance

State	Bill Number	Amount of Benefits	Contributions	Status as of April 15
California	A. 1414, A. 2129	Same as unemployment compensation	Employer, 1 per cent of wages; employee, 1 per cent of wages; state, 1 per cent of wages	In committee; no other action
California	A. 1473	Same as unemployment compensation	Employer, 1.5 per cent of wages; employee, 1.5 per cent of wages	In committee; no other action
California	A. 2097	Same as unemployment compensation	Employer, 1 per cent of wages; employee, 1 per cent of wages; state, 1 per cent of wages	In committee; no other action
Colorado	S. 21	Copy of bill not available		Dead
Massachusetts	S. 86	$12-$28 per week	Employer, 1 per cent of wages; employee, 1 per cent of wages	In committee; no other action
Massachusetts	H. 372	Same as unemployment compensation	Employer, 1 per cent of first $3,000 paid employee; employee, 1 per cent of wages up to $3,000	
Massachusetts	H. 259	Same as unemployment compensation	Included in unemployment contributions	In committee; no other action
Massachusetts	H. 260	Same as unemployment compensation	Included in unemployment contributions	In committee; no other action
Massachusetts	H. 647	Copy of bill not available		In committee; no other action
Massachusetts	H. 949	Copy of bill not available		In committee; no other action
Massachusetts	H. 1410	Copy of bill not available		In committee; no other action
Minnesota	H. 786	$7-$20 weekly	Employee, 1 per cent of wages up to $3,000; employer, none	In committee; no other action
Montana	H. 301	Same as unemployment compensation	Employer, none; employee, 1 per cent of wages up to $3,000	Dead
Nevada	A. 172	$8-$18 weekly	Employee, 1 per cent of wages up to $3,000; employer, none	Dead
New Jersey	S. 27	Same as unemployment compensation	Included in unemployment contributions	Dead

C.

Bills to Authorize Study of Health Insurance System

State	Bill Number	Status as of April 15
California	A. Res. 83	Adopted 1/26/45
California	S. Con. Res. 43	In committee; no other action
Connecticut	S. 524	In committee; no other action
Maryland	H. J. Res. 13	Dead, but did pass house 3/27
West Virginia	H. Con. Res. 4	Adopted 2/15/45

D.

Bills Proposing Constitutional Amendment to Direct Enactment of So-Called Health Service System

State	Bill Number	Status as of April 15
California	S. Const. Amend. 15	In committee; no other action
California	A. Const. Amend. 29	In committee; no other action
California	A. Const. Amend. 30	In committee; no other action

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CONNECTICUT

Service Bureau for Returning Medical Officers.—The organization of a service bureau for returning medical officers is now under way under the auspices of the Connecticut State Medical Society. It will be located and administered in the offices of the state society at New Haven and the Procurement and Assignment Service. Discharged medical officers will have access through the service bureau to factual data concerning opportunities for general or special practice in urban or rural communities, information regarding full time institutional, public health and industrial employment, and detailed intelligence on the resumption or extension of education and training. Advice and guidance concerning problems of a local nature will be available to the physician veterans at all times. Connecticut physicians who have already returned from military service will be asked to serve the bureau in an advisory capacity in order that the benefit of their special knowledge and experience may be obtained.

DISTRICT OF COLUMBIA

Award in Chemistry.—Raymond M. Hann, Ph.D., of the National Institute of Health, U. S. Public Health Service, on March 8 was presented with the Hillebrand Prize for 1944 of the Washington section of the American Chemical Society for outstanding contribution to the science of chemistry during the three preceding years. Dr. Hann received the award in recognition of his work on the chemistry, structure and synthesis of methylene and benzylidene acetals of sugar alcohols, according to *Science*.

General Ireland Honored.—A citation for distinguished service to humanity and military medicine was awarded to Major Gen. Merritte W. Ireland, formerly Surgeon General of the U. S. Army, during special ceremonies at the Medical Society of the District of Columbia, April 19. Among the speakers were Major Gen. Norman T. Kirk, Surgeon General of the Army; Vice Admiral Ross T. McIntire, Surgeon General of the Navy, and Dr. Thomas Parran, Surgeon General of the Public Health Service. The presentation was made by Dr. William M. Ballinger, acting president of the district medical society.

ILLINOIS

Public Health Meeting.—The Illinois Public Health Association will meet at the Hotel LaSalle, Chicago, May 16, and at the Hotel Abraham Lincoln, Springfield, May 17. The following program will be presented at both sessions:

Dr. Erich M. Uhlmann, Chicago, Cancer as a Public Health Problem.
Dr. Conrad S. Sommer, Chicago, Rehabilitation Program for Mental Hygiene.
Clemons M. Roark, assistant regional representative, National Housing Agency, Chicago, Housing in Illinois.
Dr. Clifton F. Hall, Springfield, Tuberculosis Control Programs in Illinois.
Dr. James G. Townsend, Bethesda, Md., Integration of Industrial Health into the Total Health Program.
Ruth Fisher, R.N., New York, What's Ahead in Public Health Nursing?
Dr. George M. Wheatley, New York, Rheumatic Fever, a Growing Public Health Problem.
Frank Stafford, U. S. Office of Education, Washington, D. C., Health, the First Objective of Education.

Dr. Leonard M. Schuman, Springfield, assistant chief, division of local health administration, and Howard J. Shaughnessy, Ph.D., president-elect, Illinois Public Health Association, Chicago, will act as chairmen. At the dinner session, Dr. Sumner M. Miller, Peoria, president of the Illinois Public Health Association, will be chairman and the speakers will include Mr. Alden B. Mills, managing editor, Modern Hospital Publishing Company, Chicago, on "Coordination of Hospital, Medical and Public Health Activities" and Dr. Reginald M. Atwater, New York, "A System of Local Health Units for the Nation."

Chicago

The Ranson Lecture.—Dr. Owen H. Wangensteen, Minneapolis, delivered the Ranson Memorial Lecture at Thorne Hall, Northwestern University, April 26, on "Studies in Etiology and Surgical Management of Ulcer." The lecture is sponsored annually by Phi Beta Pi fraternity of Northwestern University.

Arthur Compton Goes to Washington University.—Arthur H. Compton, Sc.D., professor and chairman of the department of physics and dean of the division of physical sciences, University of Chicago, and winner of the Nobel Prize for physics in 1927, has been chosen chancellor of Washington University, St. Louis. Dr. Compton was professor of physics at Washington University from 1920 to 1923.

Portrait of Ludvig Hektoen.—The fellows of the Institute of Medicine of Chicago presented an oil portrait of Dr. Ludvig Hektoen to the institute during special ceremonies April 25. The work of Carl A. E. Tolpo, the oil portrait is now hanging in the rooms of the institute, where the special program was held with Dr. William C. Danforth, president of the institute, presiding. The presentation was made by Dr. Anton J. Carlson, Frank P. Hixon professor of physiology emeritus, University of Chicago School of Medicine, and Dr. William F. Petersen gave the speech of acceptance. Jens Christian Bay, librarian of the John Crerar Library, Dr. James B. Herrick and Dr. Hektoen also spoke.

Koessler Fellowship Available.—The Jessie Horton Koessler Fellowship of the Institute of Medicine of Chicago for the aid of research in biochemistry, physiology, bacteriology or pathology will be available on September 1. The stipend is $500 a year, with the possibility of renewal for one or two years. Only such applications will be considered as are approved by the head of a department in the fields mentioned or by the director of a research institute or laboratory in Chicago and which stipulate that the recipient of the fellowship shall be given adequate facilities for carrying out the proposed research, concerning which full information is required in the application. Applications will be received up to July 1 and should be sent to Dr. Paul R. Cannon, Chairman of the Committee on the Jessie Horton Koessler Fund, 950 East 59th Street, Chicago 37. Since there are no formal blanks, application should be made by letter.

Frank R. Lillie Honored.—The Frank R. Lillie room in the Hull zoological laboratory, University of Chicago, was dedicated April 12 in tribute to Frank R. Lillie, Ph.D., Andrew MacLeish distinguished service professor emeritus of embryology at the university. The dedication ceremony was carried out with Carl R. Moore, Ph.D., chairman of the department of zoology, officiating. A portrait of Dr. Lillie, the gift of friends and painted in 1935 by Charles Hopkinson, is a feature of the room, which will be used for seminars and social gatherings. On the walls of the room also are six decorative panels of scenes of Woods Hole, Mass., where Dr. Lillie developed the Marine Biological Laboratory. Dr. Lillie, the only man ever to hold simultaneously the position of president of the National Academy of Sciences and the chairmanship of the National Research Council, was on the midway as a fellow in 1892, the year the new University of Chicago was established. With the late Charles O. Whitman, Ph.D., who established the university's department of zoology at the request of the late President William Rainey Harper, Dr. Lillie was among the first of a long line of eminent zoologists at Chicago. He succeeded Dr. Whitman as chairman of the department in 1911; he was dean of the division of biological sciences from 1931 to 1935.

INDIANA

New Executive Secretary for Lake County.—Mr. Rollis Weesner, for about twenty years associated with the attendance department of the Hammond City Schools, has been appointed executive secretary of the Lake County Medical Society. He succeeds Rollen W. Waterson, who resigned to accept a similar position with the Alameda County Medical Society, Oakland, Calif. (THE JOURNAL, March 31, p. 865).

IOWA

Harry Smith Goes to Columbia University.—Dr. Harry P. Smith, professor of pathology, State University of Iowa College of Medicine, Iowa City, has been appointed professor of pathology and executive officer of the department of pathology at Columbia University College of Physicians and Surgeons, New York. Dr. Smith has been associated with Iowa since 1930. He graduated at the University of California Medical School, San Francisco, in 1921.

Nutrition Demonstration Clinic.—Dr. Walter E. Wilkins, detailed from the U. S. Public Health Service to the nutritions program branch, Office of Distribution, War Food Administration, held a nutrition demonstration clinic at Broadlawns Polk County Hospital, Des Moines, May 3, under the auspices of the state nutrition council, the Polk County Medi-

cal Society, the Iowa State Medical Society and the state department of health. The purpose of the clinic is to give professional and other workers a more adequate concept of good and poor nutrition.

MINNESOTA

Sentenced for Narcotic Theft.—Lloyd E. Gallagher, Minneapolis, was recently sentenced by Judge Guilford in the district court of Hennepin County to serve a sentence of not to exceed seven years at hard labor in the state prison at Stillwater, following his conviction by a jury for grand larceny in the second degree arising out of a theft by Gallagher January 30 of 787 grains of morphine sulfate from the Danielson Medical Arts Pharmacy, Inc. According to the Minnesota State Board of Medical Examiners, Gallagher has a long record of narcotic violations.

Physicians Honored.—Dr. William J. Cochrane, Lake City, was honored at a meeting, April 2, for his completion of fifty years in the practice of medicine and Dr. William F. Wilson, Lake City, for his completion of fifty years as secretary of the Wabasha County Medical Society. The joint honor was a feature of a meeting sponsored by the staff of Buena Vista Sanatorium, Wabasha, whose tuberculosis commission is served as president by Dr. Cochrane, and the Wabasha-Winona county medical societies. Among the speakers were Drs. Viktor O. Wilson, Minneapolis, on "Provisions of the Revised Maternity and Infant Care Program"; Roger L. J. Kennedy, Rochester, "Multiplex Plans Proposed for the Prepayment of Medical Services," and David O. N. Lindberg, Wabasha, "A Summary of Indications for Adjunctive Surgical Therapy in Pulmonary Tuberculosis."

NEW HAMPSHIRE

State Medical Meeting.—The one hundred and fifty-fourth annual meeting of the New Hampshire Medical Society will be held at the Hotel Carpenter, Manchester, May 15, under the presidency of Dr. Fred Fernald, Nottingham. Among the speakers will be:

Dr. Henry H. Amsden, Concord, Epistaxis.
Dr. John Milne, Hanover, Infectious Mononucleosis.
Dr. Joseph S. Lawrence, Washington, D. C., director (Washington office), Council on Medical Service and Public Relations, American Medical Association, How Can Physicians Help Lawmakers?
Russell S. Spaulding, Concord, executive secretary, Blue Cross, Report on Blue Shield.
Dr. Reginald H. Smithwick, Boston, Surgical Treatment of Hypertension.
Dr. Philip D. Wilson, New York, Reconstructive Surgery of the War Wounded.
Dr. Alfred L. Frechette, Concord, Medical Relief Problems in Africa.

A feature of the meeting will be the presentation of fifty year certificates to Drs. Anna M. Littlefield, New London; William H. Mitchell, Loudon, and Henry L. Stickney, Boston.

NEW YORK

Child Guidance Institute.—On May 19 the Mental Hygiene Association of Westchester County will conduct a child guidance institute at the Sarah Lawrence College, Bronxville. The speakers will be Lois B. Murphy, Ph.D., Bronxville, on "Who are the Children Who Need Psychiatric Guidance?" Dr. Lawson G. Lowrey, New York, "Consultation and Treatment Possibilities"; Dr. Irving Edward Liss, New York, "Teachers' Problems," and Alice Kelliher, director, Walden School, New York. The Mental Hygiene Association of Westchester County was organized February 13 and was originally known as the Committee for Mental Hygiene of the Westchester County Council of Social Agencies. Constance Warren, president of Sarah Lawrence College, is president and Mrs. Ruth R. Colegrove, room 709, County Office Building, White Plains, executive secretary. One of its first activities is to work for the establishment of six tax supported mental hygiene clinics in different sections of the county under the county health department, to provide consultation and treatment for children, veterans and their families. When this is accomplished, the society hopes to continue its assistance through an advisory clinic committee. The child guidance institute is one of the many activities planned in relation to community education.

New York City

The Harvey Lecture.—Francis O. Schmitt, Ph.D., head of the department of biology and biologic engineering, Massachusetts Institute of Technology, Cambridge, Mass., will deliver the eighth Harvey Society Lecture of the current series at New York Academy of Medicine, May 17. His subject will be "Ultrastructure and the Problem of Cellular Organization."

Grant for Hodgkin's Disease.—A $5,000 grant has been given by Martha W. Hoster of Columbus, Ohio, to St. Vincent's Hospital for the Laboratory of Cellular Physiology and Pathology to conduct studies on Hodgkin's disease with collaborators at New York University, Ohio State University, Columbus, Ohio, and Walter Reed General Hospital, Washington, D. C. This fund will be administered by Dr. Antonio Rottino of St. Vincent's Hospital and Mr. Constantine G. Grand of New York University.

Physical Education Teacher Arrested for Practicing Without a License.—William James O'Connor, a physical education teacher, was arrested April 10 on a charge of unlawfully practicing medicine. Newspapers reported that he had maintained offices in various midtown hotels and prescribed treatments for wealthy patients for fees ranging from $100 to $500. A warrant for O'Connor was issued nearly a year ago in Yorkville Court but O'Connor could not be located until a state medical inspector made an appointment with him by mail through a postoffice box number in Washington. The appointment was kept April 10 and the arrest followed. The inspector said O'Connor used a stethoscope and blood pressure gage for examining him.

Meeting on Rheumatism.—The annual meeting of the New York Rheumatism Association will be held at the New York Academy of Medicine, May 9, under the presidency of Dr. Russell L. Cecil. Among the speakers will be:

Dr. John Lansbury, Philadelphia, Dietary Deficiency in the Etiology of Interstitial Calcinosis (Calcium Gout).
Dr. James A. Coss Jr., Observations on Juvenile Rheumatoid Arthritis (Still's Disease).
Drs. Hugo A. Freund and Gabriel Steiner, Detroit, Polymyositis in Rheumatoid Arthritis.
Dr. Eugene F. Traut, Chicago, Bone Marrow Findings in Arthritis.
Lieut. Col. Philip S. Hench, M. C., and Major Edward W. Boland, M. C., Rheumatic Centers of the United States Army.
Major David M. Kydd, M. C., Capt. Joseph L. Hollander, M. C., Capt. Nathan R. Abrams, M. C., and Lieut. Charles W. Fogarty Jr., M. C., Acute Arthritis Resembling Reiter's Syndrome.
Dr. Abraham S. Gordon, Brooklyn, Transmission of Gold Salts to the Fetus Through the Placenta.

Dr. Edward F. Hartung is secretary-treasurer of the association.

Postgraduate Course in Cardiology.—A postgraduate course in cardiology will be offered at Montefiore Hospital for Chronic Diseases, 150 East Gun Hill Road, in affiliation with Columbia University College of Physicians and Surgeons, June 5-August 14. Among the instructors will be Drs. Abraham Jezer, Emanuel Goldberger, Harry Gross and Joseph Ballinger. The course is designed for the general practitioner, with chief emphasis on bedside teaching and demonstration of cases to small groups of students. It will include a demonstration of cardiac fluoroscopy, of measurements of venous pressure and circulation times and discussions on criteria of classification, on correlations with pathology and on principles of treatment. This course may be taken simultaneously with elementary electrocardiography and elementary cardiovascular roentgenology. Additional information may be obtained from Dr. Willard C. Rappleye, dean, Columbia University College of Physicians and Surgeons, 630 West 168th Street, New York 32.

Personal.—Dr. Thomas M. Rivers, medical director of the Hospital of the Rockefeller Institute for Medical Research, was recently elected to honorary membership in the Royal Medical Society of Edinburgh. Dr. Rivers is now out of the United States on official duty for the U. S. Navy.——Dr. George B. Dorff, Brooklyn, retiring president of the East New York Medical Society, was recently given a special citation for his work with the selective service system of the city.——Dr. George T. Pack was recently decorated by the Brazilian government as an Officer of the Southern Cross.——Dr. Carlisle S. Boyd was recently appointed senior consulting physician and physician-in-chief emeritus of the Hospital for Special Surgery, formerly known as the Hospital for the Ruptured and Crippled. On his retirement Dr. Boyd had concluded thirty year's service with the hospital as head of the department of medicine and pediatrics (THE JOURNAL, July 29, 1944, p. 921).——Dr. Adolph G. DeSanctis has been elected an honorary member of the Bolivian Pediatric Society.

Industrial Ophthalmology in Medical Schools.—A conference in industrial ophthalmology will be held at Columbia University College of Physicians and Surgeons in conjunction with the National Society for the Prevention of Blindness, May 7-11. The course has been inaugurated in support of the government program for better visual conditions in industry. The government program was initiated by the War

Production Board and the U. S. Public Health Service in cooperation with the National Society for the Prevention of Blindness and includes as cooperating agencies the U. S. Department of Labor (Division of Labor Standards), War Manpower Commission, the Office of Vocational Rehabilitation and the U. S. Civil Service Commission. The necessity for the course arises from the present limited number of ophthalmologists available for serving industry, particularly in respect to the problems peculiar to industrial visual conditions. Members of the faculties of other medical schools have been invited in the hope of stimulating similar programs. Dr. Willard C. Rappleye, dean of the Columbia University College of Physicians and Surgeons, will open the session, which will be conducted by:

Dr. Albert C. Snell, Rochester, N. Y., Industrial Challenge to Ophthalmology.
Charles P. Tolman, New York, industrial consulting engineer, Eyesight in Industry.
Gertrude Rand, Ph.D., New York, and W. G. Darley, Illumination from the Viewpoint of Ophthalmology and of Industry, respectively.
Dr. Hedwig S. Kuhn, Hammond, Ind., Prescriptions for Occupational Glasses.
Joseph Tiffin, Ph.D., Job Analysis for Visual Requirements.
Faber Birren, New York, Use of Color for Simplifying the Visual Task.
Lieut. Comdr. Walter E. Fleischer (MC), Welding Hazards.
Dr. Leon Holland Whitney, Brooklyn, Vision, Engineering and Management.
Dr. Charles F. Kutscher, Pittsburgh, Industrial Toxic Compounds, Hazards and Treatment.
Dr. James M. Carlisle, Rahway, N. J., Industrial First Aid in Chemical Injuries of the Eye.

The program will also include a symposium on screening methods for industrial visual characteristics by Drs. Conrad Berens, New York; Joseph Lo Presti, Brooklyn, and Le Grand H. Hardy, New York.

OHIO

Bureau of Industrial Hygiene Created.—The Cleveland Bureau of Industrial Hygiene has been set up by the local division of health to help reduce health hazards in industry. The research and educational facilities of Western Reserve University School of Medicine have been made available to the new bureau, which has established quarters in room 207 at the school of medicine building on the university campus, Cleveland. The bureau was established on an order of the Cleveland welfare director as a cooperative venture of labor, industry, the medical profession and the public. Herbert G. Dyktor, former chief engineer of the bureau of industrial hygiene of the Michigan Department of Health, has been appointed director (THE JOURNAL, Sept. 16, 1944, p. 181). In the immediate future Mr. Dyktor's staff will consist of two engineers, a chemist and a secretary. As a basis for the operation of the bureau the division of health made a survey of 160,000 individuals in Cleveland manufacturing plants to determine their health status and the state of their working environment. The results of the survey have not been tabulated, although some of the more serious industrial health and accident hazards have been found to exist in newer plants that have sprung up since the war, and it is in these plants having fewer than 500 employees where the first work of the bureau will be undertaken. The survey included as one phase the filling out of questionnaires by employees regarding such things as medical examinations to which they have submitted, whether they have been examined for tuberculosis and venereal diseases and whether they were examined by a physician before going to work in their present place of employment. It is expected that much of the work of the new bureau will be educational and advisory. It will help plants in obtaining the services of physicians and nurses and in installing proper safeguards. When necessary it will use police powers of the division of health to enforce proper standards, but emphasis will be placed on lectures, movies, pamphlets and other educational work. In a statement to the press, Dr. James A. Doull, professor of hygiene and public health at the medical school, said that medical students will profit by the bureau being situated at the school, and it is hoped that the director of the bureau and members of the staff of the city division of health will contribute to instruction of the students. The bureau of industrial hygiene is an outgrowth of the cooperative effort of the health subcommittee of the mayor's war production committee, the Anti-Tuberculosis League, the U. S. Public Health Service, the Cleveland Academy of Medicine and Western Reserve University with Dr. Harold J. Knapp, commissioner of health of Cleveland. The project will aid the application of medical science to select the right man for the right job psychologically and physically.

OKLAHOMA

Personal.—Dr. Paul T. Powell, McAlester, has been named in charge of the Kay County Health Department, succeeding Dr. Joseph H. Kinnaman, who resigned to become deputy commissioner of the Nassau County Health Department (THE JOURNAL, Dec. 30, 1944, p. 1159). Dr. Jacob R. Hinshaw, McAlester, has succeeded Dr. Powell as health officer in Pittsburgh County.

Physician Hijacked.—Dr. Andre B. Carney, Tulsa, was kidnapped as he was leaving Hillcrest Memorial Hospital, February 3, shortly after midnight, according to the *Journal of the Oklahoma State Medical Association.* He was taken to the Turkey Mountain area, where he was tied to a tree. His car and money were taken. The *Journal* stated that after several hours the physician was able to free himself and walk where he could notify the police. It also stated that within the week the police captured two army deserters who were proved to be the ones responsible for the robbery and kidnapping.

Spring Clinic.—The Moton Clinical Society will conduct a spring clinic at the Moton Memorial Hospital, Tulsa, May 9-11. Among the speakers will be:

Dr. Daniel T. Rolfe, Nashville, Tenn., Vitamin Therapy in General Practice.
Dr. Walter A. Younge, St. Louis, Cardiac Emergencies.
Dr. Theodore R. Mason Howard, Mound, Bayou, Miss., Prevalence of Goiter in the Negro Race.
Dr. Ivo A. Nelson, Tulsa, Office Laboratory Procedures.
Dr. Leo Lowbeer, Tulsa, Breast Tumors.
Dr. James B. Eskridge Jr., Oklahoma City, Prenatal Care.
Dr. Grider Penick, Oklahoma City, Endocrines in Gynecology.
Dr. John F. Burton, Oklahoma City, Minor Surgery as an Office Procedure.

Dr. Rolfe will address the banquet and alumni meeting Thursday, May 10.

RHODE ISLAND

State Medical Meeting.—The one hundred and thirty-fourth annual session of the Rhode Island Medical Society will be held at the Rhode Island Medical Library, Providence, May 16-17, under the presidency of Dr. Elihu S. Wing, Providence, who will speak on "Medical Care in Rhode Island." Among the speakers will be:

Dr. Stanley P. Reimann, Philadelphia, Discussion of the Causes of Cancer.
Dr. Carl A. L. Binger, New York, Psychosomatic Medicine.
Dr. Arthur J. Geiger, New Haven, Conn., Treatment of Bacterial Endocarditis with Penicillin.
Dr. Reginald H. Smithwick, Boston, Some Experiences with the Surgical Treatment of Hypertensive Cardiovascular Disease.
Dr. Roger I. Lee, Boston, President-Elect of the American Medical Association, Geriatrics.
Dr. Elliott P. Joslin, Boston, Newer Developments in the Etiology and Treatment of Diabetes.
Dr. Frederick C. Irving, Boston, Use and Abuse of Barbiturates.
Dr. Samuel A. Levine, Boston (with four others), Coronary Artery Disease.
Dr. William R. Ohler, Boston, Clinical Application of Laboratory Facilities.
Lieut. Comdr. Jacob Gershon-Cohen (MC), and Comdr. Edgar K. Houck (MC), Derangements of the Knee Joint.
Dr. John Homans, Boston, Surgery of the Veins of the Leg—Varicosity and Some Problems in Thrombosis.
Dr. Donald G. Anderson, Boston, Clinical Uses of Penicillin.

Dr. Francis G. Blake, dean and Sterling professor of medicine, Yale University School of Medicine, New Haven, will deliver the Charles V. Chapin Oration on "Some Recent Advances in the Control of Infectious Diseases."

WEST VIRGINIA

District Health Conferences.—District conferences are being arranged by the West Virginia Public Health Association in lieu of the annual state health conference, which was canceled on account of ODT travel restrictions. The northern district meeting will be held May 21 at the Stonewall Jackson Hotel, Clarksburg, and the southern district May 28 at the Frederick Hotel, Huntington. Three topics have been selected for discussion: "Résumé of the Health Department's New Legislation" followed by a roundtable discussion of the administration of the laws, "The Pure Food and Drug Law" and "Mental Hygiene." A bill passed recently by the legislature empowers the state health commissioner to establish a bureau of mental health and to conduct mental hygiene clinics over the state. The executive committee of the public health association has announced that meetings in the northern and southern districts will also be held next fall.

Legislative Interim Committee Created.—A legislative interim committee, created for the purpose of making an overall study of public health problems, including medical and hospital care, medical care at state institutions, medical educa-

tion and prepayment hospital and medical service plans, has been named by Arnold Vickers, president of the senate, and John E. Amos, speaker of the house of delegates. The senate committee is composed of W. Broughton Johnston, Princeton; Fred C. Allen, Marlinton; Glen Jackson, Logan; G. O. Young, Buckhannon, and H. S. Boreman, Parkersburg. The house members are J. Hornor Davis, Charleston; J. Harper Meredith, Fairmont; Rush D. Holt, Weston; Everett F. Moore, Moundsville, and O. C. Hathaway, Grantsville. Speaker Amos and President Vickers will serve as members and ex officio chairman and co-chairman, respectively. An advisory committee, of which five members will be physicians, will shortly be appointed by Governor Clarence W. Meadows to serve with the legislative interim committee in this study of public health problems.

Seminars in Psychiatry Studies.—A psychiatric committee appointed recently by the president of the West Virginia State Medical Association, Dr. Thomas L. Harris, Parkersburg, is now working out a plan to hold seminars in psychiatric studies in the councilor districts. Steps have been taken to ascertain what societies will sponsor a series of meetings for a study of psychiatry as it affects the general practitioner. It is proposed to present clinical material at these meetings as the best means of teaching general practitioners what to look for and how best to handle cases that might come to their attention in the future. A special meeting was held at Huntington by the committee April 15 at which Capt. John P. Lambert, M. C., stated that the goal of the committee should be to "agree upon the best method to present to the doctors of West Virginia a common sense point of view of the meaning of psychiatry as it relates to the general practice of medicine, and to demonstrate how an understanding of psychiatry can be of inestimable value to the physician in his daily practice." The committee, which will meet again in Huntington May 20, is composed of Dr. Oscar B. Biern, Huntington, chairman; James L. Wade, Parkersburg; Edward J. Van Liere, Morgantown; Edward F. Reaser, Huntington, and Archer A. Wilson, Charleston, in addition to Captain Lambert, a member ex officio.

GENERAL

William McNett Named Art Director.—William Brown McNett, Philadelphia, has been appointed art director of the medical and scientific division of the Blakiston Company, Philadelphia. Mr. McNett has in time past served as assistant in the department of art as applied to medicine, Johns Hopkins University School of Medicine, Baltimore, and director of the department of medical art, Temple University School of Medicine, Philadelphia.

Committee Named to Aid Leprosy Program.—Luther H. Hodges, New York, vice president, Marshall Field and Company, national chairman of the postwar antileprosy program of the American Mission to Lepers, has named a sponsoring committee to work with him in promoting the program and to raise $500,000 needed. Mrs. Harper Sibley, Rochester, N. Y., is chairman of the committee. Other members of the committee include prominent physicians throughout the country.

Report on Prevention of Blindness.—The National Society for the Prevention of Blindness expended $169,578 in 1944, allowing $16,341 of the $185,919 income to be transferred to the reserve fund, according to its recently released thirtieth annual report. During the year the society sponsored three hundred and fifty broadcasts by radio stations throughout the country, produced a documentary film entitled "Eyes for Tomorrow," which was shown about six hundred times in more than twenty states, and carried on other mediums of educational activity. One of the permanent developments in the conservation of eyesight in industry is the society's participation in the drive of the War Production Board to speed up production through improvement of visual conditions in war industries.

Squibb and Ciba Prizes Announced.—The Association for the Study of Internal Secretions has announced that the Squibb Award has been given to Edward C. Kendall, Ph.D., professor of biochemistry and head of the section, University of Minnesota Graduate School, Minneapolis-Rochester, for his fundamental contributions to endocrinology, in particular the isolation of thyroxine from the thyroid gland and his recent observations on the fractionation and functions of active principles of the adrenal cortex. Dr. Kendall was president of the Association for the Study of Internal Secretions in 1930. The Ciba Award, also announced through the Association for the Study of Internal Secretions, has been given to Jane Anne Russell (Mrs. Alfred E. Wilhelmi), Ph.D., instructor in physiologic chemistry, Yale University School of Medicine, New Haven, for her fundamental observations on the role of the anterior pituitary, adrenal and thyroid glands in the absorption and utilization of sugars and starches. One prize is made available by E. R. Squibb and Sons and the other by Ciba Pharmaceutical Products. Dr. Kendall received his Ph.D. at Columbia University, New York, in 1910 and Dr. Russell from the University of California, Berkeley, in 1937.

Academy of Sciences Receives Award.—The American Design Award, presented by Lord & Taylor and consisting of a certificate and a check for $25,000, was given to the National Academy of Sciences at a luncheon, April 19, in recognition of the collective achievements of American scientists "in supplying the arsenal of democracy with the greatest war weapons the world has ever seen," according to the New York *Times*. The award particularly honored six American scientists who composed the scientific "high command" for the various government created agencies established to mobilize American brain power for the creation of new weapons, new airplanes and vehicles, new medicines, new materials and countless other victory tools, many of them still secret, that have made victory possible. At the request of these six persons the award was presented to the academy as the body that represents all scientific endeavor in America. The six persons representing this "scientific high command," are:

Dr. Vannevar Bush, Sc.D., Washington, D. C., director, Office of Scientific Research and Development.

James Bryant Conant, LL.D., Cambridge, Mass., chairman, National Defense Research Committee (absent from the luncheon because of illness).

Karl T. Compton, Ph.D., Cambridge, chief of the field service for the National Defense Research Committee.

Dr. Alfred Newton Richards, chairman, Committee on Medical Research, Office of Scientific Research and Development.

Jerome C. Hunsaker, D.Sc., Boston, chairman, National Advisory Committee for Aeronautics.

Dr. Ross G. Harrison, chairman, National Research Council, Washington, D. C.

LATIN AMERICA

Health Activities in Latin America.—*Meeting on the Prevention of Blindness.*—The Asociacion para Evitar la Ceguera en México (Mexican Society for the Prevention of Blindness) is planning to meet in Mexico City, August 13-18. Among the speakers who will address the session will be Dr. Andrew Rados, Newark, N. J., on "Heredity Anomalies of the Lens Coupled with Systemic Disturbances."

Outbreak of Cerebrospinal Meningitis.—Barbados, B. W. I., health authorities are waging a vigorous campaign to check the epidemic of cerebrospinal meningitis, which flared up after the return of a thousand agricultural contract workers from the United States. Thirty cases, 5 of which resulted in death, have been detected on the island to date. The afflicted natives are being isolated on Pelican Island.

Society News.—Dr. Gonzalo E. Arostegui was recently elected president of the Sociedad Nacional de Cirugía of Havana. Other officers include Drs. Vicente Banet, vice president, José I. Tarafa, secretary, and José Lastra, treasurer.——New officers of the Sociedad Argentina de Tisiologia for 1945 include Drs. Ismael N. Hernandez, president, Oscar A. Vaccarezza, vice president, Alvaro E. Bence, secretary, and Oswaldo N. Garré, treasurer.

Visitors to the United States.—Dr. Edmundo Vasconcellos, chairman of the department of clinical surgery, Faculty of Medicine of the University of São Paulo, Brazil, went to the United States recently for a three months tour throughout the country as the guest of the Department of State. Dr. Joseph P. Buteau, Port au Prince, director of the Haitian Red Cross, is also a guest of the Department of State in the tour of certain centers in the country. Another guest is Dr. Hermán Posada González, director of the University of Antioquia, Medellín, Colombia. Dr. Desiderio Gross, Chile, has gone to New York to study heart ailments.

Traveling Health Exhibition.—The Colombian government has authorized the Cleveland Health Museum to duplicate seventy-three units of its exhibits to be used as a traveling health exhibition in Colombia. Among the group will be displays on preventive dentistry, tuberculosis, conservation of hearing and of eyesight, general biology of the human body and a complete duplicate of the nutrition exhibit "Food for Health." This nutrition exhibit was duplicated for the Mexican government in 1943. According to Dr. Ricardo Charria, Bogota, who visited the museum last year under the sponsorship of the Office of the Coordinator of Inter-American Affairs and who arranged for the exhibit, principal health hazards in Colombia are malaria, intestinal parasites and water borne diseases, tuberculosis, venereal diseases, yaws and smallpox.

The Scheme for a National Health Service: Negotiations with the Government

A year ago the government put forward proposals for a national health service which have been described in THE JOURNAL. The medical profession and particularly the British Medical Association were opposed to them. There was intense dislike of the suggestion that the work should be organized by a lay body and of any infringement of the right of private practice. A committee representing the British Medical Association, the colleges and other medical bodies was appointed for this purpose and since early in January has held nine meetings, of which eight have been attended by members of the Ministry of Health representing the government. The representatives of the profession contended that the national health service should be brought into being by stages, beginning with the development of the hospital and consultant services and with the extension of the nonhospital services on the basis of the present national health insurance system. No decision was reached on this and other points raised by the negotiating committee, which is now seeking the views of its constituents on a number of possible changes in the central and local administrative structure and other aspects of the White Paper. When the medical profession, the local authorities and the voluntary hospitals have completed this consultation with their members, the negotiations with the Ministry of Health will be resumed. Only then will the question arise of government decision on the proposals to be submitted to Parliament.

The Council of the British Medical Association has received the report of its negotiating committee and will make a full report with recommendations to a special representative meeting to be held on May 3 and 4. The report of the negotiating committee is a confidential document which cannot be published, but it has been sent to every member of the medical profession, whether a member of the British Medical Association or not. The council has also decided to request the divisions of the association to make arrangements for early meetings of the profession to discuss the report and instruct representatives. Statements have been made in the public press that the government has "surrendered to the doctors," but these are, to say the least, premature. All that can be said is that the government has not turned down the proposals made by the representatives of the profession. When it is clear that these have the support of the medical profession as a whole, the government will decide to what extent they are acceptable.

A Distinguished Medical Woman

Dr. Janet M. Vaughan, a well known hematologist, whose book "The Anemias" is in its second edition, has been appointed principal of Somerville College (a women's college), Oxford. Dr. Vaughan is medical officer in charge of the North West London Blood Supply Depot for the Medical Research Council. She was an undergraduate of Somerville College and took a first class in physiology in 1922 and her D.M. degree in 1930. She has been a Rockefeller fellow, a Beit memorial fellow and a Leverhulme fellow. She has held the post of assistant pathologist at University College Hospital, and the British Postgraduate Medical School. She was a member of the Interdepartmental Committee on Medical Schools and is a member of the Royal Commission on Equal Pay for Women and of the body appointed by the government to investigate public health in India.

Decrease of Incidence of Alcoholic Cirrhosis

Pasteur Vallery-Radot and his collaborators have recorded the number of cirrhoses of alcoholic origin admitted in the service of the medical clinic of the Bichat Hospital since 1938, when the consumption of wine and alcohols was not restricted, until 1944. The decrease between 1938 and 1944 is 87 per cent.

At the Société médicale des hôpitaux Heuyer pointed out that the number of cases of acute alcoholism, notably delirium tremens, increased suddenly in Paris during the first days of mobilization in 1939, again at the time of the German victory, during the invasion and at the exodus in May and June 1940. The maximum was observed on June 14, 1940, the day the Germans entered Paris. But during the weeks which preceded the liberation and during the days of street fighting at the end of which the Germans evacuated the capital, arrests for acute alcoholism were rare and not a single case was observed during August, the month of liberation. The psychoses in general and notably the alcoholic psychoses have greatly diminished in France during the course of the war.

Decourt and Phibet have made the same observations. Up to the outbreak of war in the pavilion for the mental cases in the Hospital of Saint Anthony 48 per cent were alcoholic. Since then the number of cases of alcoholic dementia has been reduced by 50 per cent.

Raynaud's Disease

De Fourmestraux reports 3 cases of pure Raynaud's syndrome in which he has obtained favorable results by repeated infiltrations of the stellate ganglion, of the cervical sympathetic chain and of the lumbar ganglions. From the rapid improvement of painful symptoms following ganglionic blockage he has concluded that functional disturbances are involved. If the initial lesions in Raynaud's disease were primarily arterial, the vasodilatation produced by the intervention would have had only a weak and temporary influence.

The removal of the stellate ganglion apparently should be reserved for the grave forms of Raynaud's disease, which are rare. The suppression of the stellate ganglion produces a Claude Bernard-Horner syndrome, which unfortunately remains permanent. It involves the disappearance of certain elements of the cervicothoracic chain: lacrimal, salivary and ocular and particularly coronary and pulmonary vasomotor fibers. Section of the splanchnic nerves and resection of the second lumbar present less inconvenience. It is advisable to consider the relative gravity of Raynaud's disease. Surgical intervention should not be resorted to until after repeated infiltrations, which will have the advantage of confirming the diagnosis and, at little expense, may lead to a cure, which may be complete.

Polyvalence of Bacterial Toxins

H. Vincent of the Académie des sciences states that the toxins secreted by pathogenic agents are usually considered specific in nature in spite of the diversity of symptoms which they cause. This view simplifies the concept of the infectious role of bacteria. The colon bacillus, for instance, secretes at least two toxins, one which becomes fixed to the intestine and another to the central nervous system. It is the same with the bacillus of typhoid, Vincent says; one of the toxins which it secretes, besides being labile, is toxic to the nervous system, and the other is a resistant enterotoxin capable of provoking in animals an acute adrenalism with renal inhibition. These toxins are further differentiated in that it is easy to produce immunization against the enterotoxin but not against the neurotoxin.

MOSCOW

Systematic Killing by Germans of the Mentally Deranged

Goldovsky, Colonel of Medical Service Red Army, and Pratonov, Colonel of Medical Service Red Army, have made the following report relative to a psychiatric hospital captured near Berlin:

Oberwalde Meseritz was the first psychiatric medical institution we found on the approaches to Berlin. In the buildings we found a comfortable receiving room, a splendid director's office and a number of rooms for administration with shelves full of case histories and daily reports. On the second floor were a gymnasium and a cinema. There were special x-ray rooms and laboratories. Buildings for patients contained bright wards, large and small separate rooms for one day patients, rest nooks and a dining room. Gardens were planted around some of the buildings and were surrounded by high stone walls. There were bars across the windows.

The life of the patients presented a sharp contrast to these comfortable surroundings. They wandered over the entire territory in groups and singly, carrying cups and plates, walking into kitchens in search of food and drink. They wandered from one building to another and to the offices of administration. Among them we saw neurasthenics and people suffering from Parkinson's disease, maniacs and schizophrenics. However, there were some who looked like perfectly healthy people. They helped us to bring order among the thousands of patients who had been left to the mercies of fate. There was no medical personnel. Doctors, nurses and orderlies had run away at the approach of our troops, fearing retribution for their crimes.

The first conversations revealed the mass organized destruction of patients or people considered by authorities as undesirable. We were detained in Oberwalde and saw for ourselves what had gone on in the hospital. People were questioned who had been confined to the hospital for antifascist statements and "incorrigible behavior," defiling the purity of Aryan blood. We examined the record book of patients and files of case histories. Finally we succeeded in questioning some of the culprits.

The Germans began to concentrate mentally deranged patients in Oberwalde in 1940, bringing them in groups of 100 to 300 by railroad from zones of action of allied aviation. There were times when the number of patients in the hospital reached 5,000. This flow of patients continued until January 1945, yet we found no more than 1,000. Where were the others?

A register of deaths during these years gives a detailed answer to the question. The last entry bears the number 18,232. Registered in the book for 1944 alone are the reception of 3,948 patients and the death of 3,814. If the capacity of the hospital was not overtaxed, it was due solely to this unheard of high death rate (97 per cent) in a medical institution. The files yielded copies of notices sent to relatives informing them of the death of patients and confirmed the figures precisely.

The entries showed that death resulted in the majority of cases from seven to ten days after the arrival of the patient. Causes of death are most commonly blood poisoning resulting from boils and exhaustion. Platonov, Colonel of the Medical Service, P. Shkarabsky, who is a forensic expert, and Major A. Marants, pathologic anatomist, worked to define the causes of the death in corpses exhumed. The burial ground itself was eloquent evidence. Under neat rows of gravestones creating a lyrical picture of "eternal peace" we found long pits in which four to five rows of naked bodies were piled. In rare cases pathologic anatomists found that the cause of death was tuberculosis, pneumonia or heart failure. All others were victims of "Aryan psychiatrists."

In the doctors' offices we found kilogram packages of medinal and veronal (both barbiturates) and large boxes of 100 ampules of scopolamine and morphine. Patients called these offices todzimmer (death rooms). In them systematic murder of the victims of Oberwalde was carried out.

We had our findings confirmed when we captured Rataichak, the head nurse of the women's department, in a neighboring city. Rataichak is a member of the Fascist party. With indescribable callousness she informed us: "I worked here almost twenty years. At the beginning of the war cases of killing of mentally deranged were rare. In 1941 when Walter Grabovsky was appointed director these killings became more and more frequent. True, Grabovsky was not a doctor, but he was a high official in the National Socialist Party. Head doctor Mooz, also prominent National Socialist, during his rounds would point out to the chief of the department those patients who were to be taken first to the office for treatment and then to the eighteenth department, from which corpses were taken to the graveyard. Some were buried on the premises; others were sent to Frankfort for cremation (construction of a crematorium had only been begun in Oberwalde). Poisoning in the women's department was carried out in the following manner: I took the patient to the office, took 3 tablespoons of veronal or medinal from a package and dissolved it in a glass of water. Some women had to be held by orderlies when they drank the mixture. If the patient resisted, we had to use a feeding tube. Sometimes this procedure made the patient's nose bleed. Particularly fractious patients were injected with scopolamine and morphine. Patients died quietly."

She admitted that she had personally poisoned between 1,000 and 1,500 people.

We also succeeded in finding and questioning an orderly named Gulke from the men's department. His work was to help doctor's assistant Weideman fill injection needles with a mixture of five ampules of scopolamine and five ampules of morphine and to hold the patient while this lethal dose was injected into him."

A dentist named Rosenberg, suffering from encephalitis, said "I managed to escape injection by sending for my dental equipment and treating staff and patients free."

The personal "villa" of Walter Grabovsky with secret office and personal laboratory, experimental animals, various poisons and dozens of urns of burned corpses is worthy of special detailed investigation. Everything in it confirms the stories told of him as a Fascist organizer of murder of many thousands of people. Clues led from this villa to the former place where Grabovsky worked in Kalisz. He brought with him from there a copy of the register of thousands of deaths of mentally deranged patients who had died in institutions he headed.

Marriages

JAMES A. JACKSON, Madison, Wis., to Miss Thelma Klemm of Platteville in Chicago, February 10.

ALVIN BEYER Jr., Houston, Texas, to Miss Mary Tom Luton of Grand Prairie, January 27.

GEORGE J. MALOOF to Miss Elizabeth Mary Rowley, both of Madison, Wis., December 30.

WILLIAM JAMES FINK to Miss Kay Kerlin, both of Washington, D. C., March 5.

MARIO V. BISORDI to Miss Nina Stucky, both of Mount Vernon, N. Y., April 8.

MARTIN FISHKIN to Miss Jewel Rosenthal, both of Chicago, March 10.

Deaths

Thomas Ellwood Buckman ⊕ Jacksonville, Fla.; Harvard Medical School, Boston, 1917; specialist certified by the American Board of Pediatrics, Inc.; member of the American Pediatric Society, American Academy of Pediatrics and American Society for Clinical Investigation; was chairman of the public relations committee, Florida Medical Association, in 1934 and of the health committee of the Duval County Council Agencies *from 1935 to 1937*; member of the American Commission on Standardization of Biological Stains from 1922 to 1926 and in 1930 member of the section on hematology, White House Conference on Child Health and Development; president of the Duval County Medical Society in 1939; assistant in medicine from 1920 to 1922, assistant in pediatrics from 1922 to 1925 and instructor 1924-1925 at his alma mater; since 1926 director of infant welfare stations, city board of health; member of the Duval County Welfare Board; served during World War I; from 1922 to 1925 assistant physician, Huntington Memorial Hospital, Harvard University; from 1922 to 1925 director of the blood research laboratory and visiting pediatrician at the Boston City Hospital, where he was assistant at the Thorndike Memorial Laboratory in 1924-1925; visiting physician at the Massachusetts State Infirmary and director of laboratories at the Robert Brigham Hospital, Boston, 1924-1925; president of staff, Riverside Hospital, 1933-1934; member of the board of directors of the Hope Haven Hospital; since 1939 director of the King Edward Nursery; consultant in contagious diseases, Brewster Hospital; secretary of the staff, Duval County Hospital; visiting pediatrician at St. Vincent's Hospital, where he died March 26, aged 53, of virus infection of the intestinal tract.

Sidney Jonas Wolfermann ⊕ Fort Smith, Ark.; Northwestern University Medical School, Chicago, 1911; Army Medical School, 1918; member of the House of Delegates of the American Medical Association in 1944; president of the Arkansas Medical Society, 1938-1939, councilor of the society from 1932 to 1938 and chairman of the council in 1936-1937; served as president of the Sebastian County Medical Society; councilor of the Southern Medical Association from 1939 to 1944; fellow of the American College of Surgeons; director of the Arkansas Tuberculosis Association; director and past president of the Sebastian County Tuberculosis Association; past president of the Sebastian County Crippled Children's Society; during World War I served in the medical corps of the U. S. Army; interned at St. Louis City Hospital in St. Louis; an organizer of the Cooper Clinic at Fort Smith and associated with it since its inception in 1920; director of the Hospital for Crippled Adults, Memphis, Tenn.; on the staff of St. Edward's Mercy Hospital; past president of the Fort Smith Rotary Club; died February 18, aged 56, of coronary disease.

Marcellus A. Walker, Paris, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1901; member of the American Medical Association; held all the offices of the Lamar County Medical Society at various times; formerly president of the North Texas District Medical Society; health officer of Paris from 1905 to 1913; served as physician in charge of the clinic operated by the Lamar County Tuberculosis Association from the time of its establishment until his death; member of the staff of the Lamar County Hospital, serving as president of the board of managers from the time of its organization until 1931; a charter member of the Lions Club; member and past president of the staff of St. Joseph Hospital, where he died January 23, aged 67, of cerebral hemorrhage.

Georg Barkan, *Brookline,* Mass.; Ludwig-Maximilians-Universität Medizinische Fakultät, Munich, Bavaria, 1917; assistant professor of biochemistry at Boston University School of Medicine; served as a surgeon in the German army during World War I; after a period of teaching and research appointments with the Universities of Munich, Würzburg and Frankfort-on-the-Main, he was appointed professor of pharmacology and director of the Pharmacologic Institute at the University of Tartu (Dorpat) in Estonia, remaining there until 1937; came to this country in 1938; contributed extensively to the European and American literature on pharmacology and biochemistry particularly in relation to the nonhemoglobin iron compounds of the blood; died March 7, aged 55.

Frederick McGregor Hartsock ⊕ Colonel, U. S. Army, retired, Washington, D. C.; Columbian University Medical Department, Washington, 1897; entered the U. S. Army as an assistant surgeon in July 1898; promoted through the various ranks to that of colonel; retired on May 31, 1939; veteran of the Spanish-American War; served in the Philippines during the insurrection and was attached to the American Embassy at Peking, China; served during World War I; at one time on the staff of the United States Soldiers' Home Hospital; fellow of the American College of Surgeons; died March 7, aged 69, of biliary cirrhosis and pneumonia.

John Carl Grill ⊕ Milwaukee; Medizinische Fakultät der Universität Wien, Vienna, Austria, 1921; professor and director department of pathology at the Marquette University School of Medicine; specialist certified by the American Board of Pathology, Inc.; member of the American Association of Pathologists and Bacteriologists and the American Society of Clinical Pathologists; fellow of the American College of Physicians; director of the pathologic laboratories, Milwaukee County Hospital, Wauwatosa; pathologist on the staffs of St. Joseph's and St. Mary's hospitals; died March 17, aged 52, of cerebral hemorrhage.

Frank V. Brownell, Canajoharie, N. Y.; Albany Medical College, Albany, 1882; member of the American Medical Association; in 1906 president of the Montgomery County Medical Society, which in 1934 gave a dinner in his honor celebrating his completion of fifty years of medical practice; at one time city health officer of Schenectady, where he had been on the staff of the Ellis Hospital; for many years a member of the board of education of Canajoharie; served as physician for the New York Central Railroad and for the Beech-Nut Packing Company; died March 4, aged 88, of pulmonary congestion.

Thomas Willett ⊕ West Allis, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1903; served overseas during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; formerly associated with the U. S. Public Health Service Reserve; at one time lecturer in histology and embryology at his alma mater; associate, American College of Physicians; member of the American Heart Association and the American Association for the Advancement of Science; a director of the Milwaukee County Bank at West Allis; died February 25, aged 67, of myocardial fibrosis.

George Henry Steinle ⊕ Burlington, Iowa; St. Louis University School of Medicine, 1917; member of the American Urological Association; served during World War I; began active duty as a captain in the medical reserve corps of the U. S. Army on Dec. 12, 1940, serving as chief of the urologic section of the Station Hospital, Camp Joseph T. Robinson, Ark.; relieved from active duty on July 31, 1941; on the staffs of the Burlington Hospital, St. Francis Hospital and the Mercy Hospital, where he died February 11, aged 52, of cardiorenal disease.

William Elmer Bannister ⊕ Lexington, Ky.; Kentucky School of Medicine, Louisville, 1892; past president of the Fayette County Medical Society; interned at the St. Joseph Infirmary in Louisville; member and past president of the staff of St. Joseph Hospital; member of the staff of the Good Samaritan Hospital, where he died March 1, aged 74, of angina pectoris.

Tom Randolph Barry ⊕ Knoxville, Tenn.; Vanderbilt University School of Medicine, Nashville, 1915; past president of the Tennessee State Medical Association; member of the American Urological Association; fellow of the American College of Surgeons; specialist certified by the American Board of Urology, Inc.; served overseas during World War I; interned at Bellevue Hospital in New York; urologist at the Knoxville General, St. Mary's Memorial and Fort Sanders hospitals; died March 5, aged 57, of coronary occlusion.

Adelheid C. Bedal, St. Louis; Woman's Medical College of Pennsylvania, Philadelphia, 1891; member of the American Medical Association; died in the Jewish Hospital March 20, aged 84, of heart disease.

William Hurlburt Bennett, Norwell, Mass.; Baltimore University School of Medicine, 1892; member of the American Medical Association; died in Boston March 5, aged 76, of acute dilatation of the heart and diabetes mellitus.

Harvey Allen Berkey ⊕ Elmhurst, Ill.; Chicago College of Medicine and Surgery, 1913; member of the American Urological Association; past president of the Chicago Urological Society; served during World War I; formerly on the staff of the Oak Park Hospital, Oak Park; died March 25, aged 72, of acute pulmonary edema.

Lewis Elmer Bratt, Akron, N. Y.; Chicago College of Medicine and Surgery, 1911; health officer of the village of Akron and town of Newstead; died in the Lockport City Hospital, Lockport, March 23, aged 63, of coronary occlusion.

Ephraim Mays Brevard, Tallahassee, Fla.; University of Maryland School of Medicine, Baltimore, 1894; member of the American Medical Association; veteran of the Spanish-American War; died February 26, aged 74, of cerebral hemorrhage, diabetes mellitus and mitral regurgitation.

Charles Franklin Brown ⊕ Salisbury, Md.; Maryland Medical College, Baltimore, 1912; died suddenly March 25, aged 62, of coronary thrombosis.

John Henderson Burlingame, Evanston, Ill.; Rush Medical College, Chicago, 1878; Civil War veteran; practiced in Cherokee, Iowa, for forty-seven years and served ten years as mayor; died March 10, aged 97, of heart failure.

John Edward Butler, Taunton, Mass.; Harvard Medical School, Boston, 1891; member of the American Medical Association; died March 9, aged 81, of arteriosclerosis.

Stephen A. Cambourn, Chicago; Northwestern University Medical School, Chicago, 1897; member of the American Medical Association; died March 8, aged 73, of obstruction of the bowel with perforation and general peritonitis.

Carl James Cannon, Cleveland; Cleveland Homeopathic Medical College, 1899; member of the American Medical Association; on the staff of the Huron Road Hospital, East Cleveland, where he died March 7, aged 69, of cardiac failure.

Sumner Coolidge, Middleboro, Mass.; Harvard Medical School, Boston, 1900; from 1905 to 1908 colonel in the army, serving as executive officer for the chief sanitation engineer for the Panama Canal; for many years medical superintendent of the Lakeville State Sanatorium; died in St. Luke's Hospital March 10, aged 85, of coronary occlusion, bronchopneumonia and cerebral embolism.

Thomas Francis Cotter ⊕ East Chicago, Ind.; Medical College of Indiana, Indianapolis, 1902; fellow of the American College of Physicians; served as an acting assistant surgeon in the U. S. Public Health Service; on the staff of St. Catherine's Hospital; died in St. Luke's Hospital, Chicago, March 12, aged 67, of pneumonia.

William Henry Crothers, Campbell, Calif.; Cooper Medical College, San Francisco, 1895; died in Saratoga February 21, aged 79, of cerebral hemorrhage.

William Parish Curtis, St. Louis; Howard University College of Medicine, Washington, D. C., 1891; on the staffs of the Homer G. Phillips' Hospital, St. Mary's Infirmary and the Peoples Hospital, where he died February 23, aged 78, of hypertension.

Joseph Henry Davis, Macomb, Ill.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1901; member of the American Medical Association; on the staffs of the Phelps Hospital and St. Francis Hospital, where he died March 4, aged 69, of sclerosis of the liver.

Lavinia R. Davis, Pulaski, N. Y.; Syracuse University College of Medicine, 1896; member of the American Medical Association; practiced in Oneida for many years; died February 8, aged 81, of cerebral hemorrhage.

Claus Gilbert Delfs, Geneva, Neb.; John A. Creighton Medical College, Omaha, 1913; on the staff of the Lutheran Hospital, York, where he died February 1, aged 51, of coronary sclerosis.

Samuel DeRamus, Cincinnati; Meharry Medical College, Nashville, Tenn., 1918; died March 8, aged 54, of heart failure and pulmonary edema.

Francis Albert Bennett Donlan, Metuchen, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1912; member of the American Medical Association; on the staff of St. Peter's Hospital, New Brunswick, where he died February 6, aged 58, of neoplasm of the mediastinum.

James Lafayette Donnan, Ware Shoals, S. C.; University of Georgia Medical Department, Augusta, 1891; member of the American Medical Association; died February 1, aged 77, of hemiplegia.

Godlove Grover Eckhart ⊕ Marion, Ind.; Jefferson Medical College of Philadelphia, 1907; died in the Marion General Hospital February 26, aged 62, of chronic glomerular nephritis and diabetes mellitus.

Robert Hite Egbert ⊕ Martinsville, Ind.; Indiana University School of Medicine, Indianapolis, 1909; served as president of the Morgan County Medical Society; medical director of the Home Lawn Mineral Springs; died March 22, aged 60, of carcinoma of the pancreas.

Laurens Enos, Jerseyville, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1891; served during World War I; died February 19, aged 82, of senility.

Eugene William Erler ⊕ South Orange, N. J.; Columbia University College of Physicians and Surgeons, New York, 1907; served on the staffs of the Presbyterian Hospital in Newark, East Orange Hospital, East Orange, and the Orange Memorial Hospital, Orange, where he died March 17, aged 62, of coronary occlusion.

Charles Cornelius Fenstermacher, Three Rivers, Mich.; College of Physicians and Surgeons of Chicago, 1893; on the staff of the Three Rivers Hospital; died March 5, aged 75, of uremia following a prostatectomy.

Edmund R. Gaddie, New Albany, Ind.; Louisville National Medical College, Medical Department State University, Louisville, Ky., 1892; died March 11, aged 74, of cerebral hemorrhage.

Louis Harrington Gibbs, Scranton, Pa.; Bellevue Hospital Medical College, New York, 1873; member of the American Medical Association; died in the West Side Hospital February 9, aged 98, of fracture of the left humerus and left femur incurred in a fall.

Clark Hutchinson Gordon ⊕ Trenton, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1897; died February 24, aged 72, of coronary occlusion.

Wilbur Clarence Gordon, Los Angeles; Howard University College of Medicine, Washington, D. C., 1904; died February 1, aged 64, of coronary occlusion.

Elias Bush Guile, Utica, N. Y.; Homeopathic Hospital College, Cleveland, 1888; member of the American Medical Association; president of the Oneida County Historical Society; member of the city board of education; on the staff of the Utica Memorial Hospital, where he died March 28, aged 78, of cardiorenal syndrome.

Edward Humes Harris, Snow Shoe, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1900; member of the American Medical Association; surgeon for the Pennsylvania and New York Central railroads and various coal companies; died in the Bellefonte Hospital, Bellefonte, March 29, aged 70, of myocarditis.

Maxwell Herschleder ⊕ Gary, Ind.; Illinois Medical College, Chicago, 1910; owner of the Lincoln Hospital; on the staffs of the Methodist and St. Mary's Mercy hospitals; killed March 9, aged 60, when his automobile was struck by a train.

Ralph Ward James ⊕ Winfield, Kan.; Northwestern University Medical School, Chicago, 1905; fellow of the American College of Surgeons; served during World War I; visiting physician at the William Newton Memorial Hospital and St. Mary's Hospital, where he died February 2, aged 64, of cerebral hemorrhage.

Howard H. Johnson, St. Albans, Vt.; University of Vermont College of Medicine, Burlington, 1906; member of the American Medical Association; president of the staff of St. Albans Hospital; died December 23, aged 70, of injuries received in an automobile accident.

Louis Jordy, York, Pa.; Jefferson Medical College of Philadelphia, 1892; died in the York Hospital February 5, aged 76, of chronic nephritis.

Leon Lamont Kelley, Middleville, N. Y.; Syracuse University Medical College, New York, 1918; member of the American Medical Association; health officer of five communities in Herkimer County; president of the school board and the Middleville Bank; served on the staff of the Hospital of the Good Shepherd, Syracuse University and the Herkimer Memorial Hospital in Herkimer; died February 16, aged 51, of heart disease and arthritis.

Albert James Maris, Long Beach, Calif.; Medical College of Indiana, Indianapolis, 1892; died in a local hospital February 22, aged 77.

Bernard Joseph McEntee, Wilmington, Del.; University of Pennsylvania School of Medicine, Philadelphia, 1911; member of the American Medical Association; served overseas during World War I; chief of staff at St. Francis Hospital; died in St. Joseph's Hospital, Lancaster, Pa., February 24, aged 58, of bronchiectasis.

Evelyn Mae Gruhlke McLane ⊕ Jackson, Minn.; Rush Medical College, Chicago, 1930; on the staff of the Minnesota Colony, Cambridge; died February 16, aged 42.

Roy Clark Meals, Oil City, Pa.; University of the South Medical Department, Sewanee, Tenn., 1904; served during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; formerly associated with the U. S. Veterans Bureau; died December 17, aged 65, of heart disease.

Otto Ernest Meyer, Chicago; Illinois Medical College, Chicago, 1905; member of the American Medical Association; died February 19, aged 76, of mitral regurgitation.

Andrew G. Minnick, Lock Springs, Mo.; University Medical College of Kansas City, 1900; served as mayor and member of the school board; formerly county coroner; local surgeon for the Rock Island Railroad; died February 14, aged 74, of angina pectoris.

Andrew Francis Moynihan, Sauk Centre, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1903; served as a captain in the medical corps of the U. S. Army in France during World War I; city physician of Sauk Centre and deputy coroner of Stearns County at the time of his death; died April 11, aged 71, of cerebral hemorrhage.

John Alexander Neil, Chicago; Chicago College of Medicine and Surgery, 1910; died in Tampa, Fla., January 30, aged 65, of coronary thrombosis.

Henry Waldo Power, Conrad, Mont.; Northwestern University Medical School, Chicago, 1903; member of the American Medical Association; fellow of the American College of Surgeons; interned at the Mercy Hospital in Chicago; founded the first hospital in Conrad, which was expanded into the present St. Mary's Hospital, where he was the chief surgeon; died April 3, aged 65, of bronchogenic carcinoma.

Charles Corwin Rowley, Thompsonville, Ill.; Denver Homeopathic College, 1904; member of the American Psychiatric Association; formerly on the staffs of the Anna State Hospital in Anna and the Dixon State Hospital in Dixon; at one time prison physician at Menard; died February 23, aged 62, of cerebral hemorrhage.

William H. Shelton, Guin, Ala.; Memphis (Tenn.) Hospital Medical College, 1901; died February 1, aged 76, of carcinoma.

James Evart Derreckson Silcox, Keyport, N. J.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1907; for many years medical examiner in the Keyport schools; died February 1, aged 74, of coronary occlusion.

John William Smith, Branchville, Va.; University of Maryland School of Medicine, Baltimore, 1906; member of the American Medical Association, surgeon for the Seaboard Air Line Railway; died in Norlina, N. C., February 25, aged 73, of coronary disease (cardiorenal).

Joseph Smith ⊕ Brooklyn; Jefferson Medical College of Philadelphia, 1904; member of the American Psychoanalytic Association and the American Psychiatric Association; served as president of the Brooklyn Neurological Society; specialist certified by the American Board of Psychiatry and Neurology; on the staffs of the Jamaica Hospital, Jamaica, Kings County and Unity hospitals; died in the New York Post-Graduate Hospital, New York, February 26, aged 67, of carcinoma of the intestine.

Carl John Snitkay ⊕ Belle Plaine, Iowa; State University of Iowa College of Homeopathic Medicine, Iowa City, 1901; fellow of the American College of Surgeons; served during World War I; on the staff of the Corn Belt Hospital; died February 5, aged 70, of uremia.

Jesse Batts Sory, Fredonia, Ky.; University of Nashville (Tenn.) Medical Department, 1901; also a druggist; served during World War I; died in St. Thomas Hospital, Nashville, Tenn., February 16, aged 67, of Hodgkin's disease and bronchopneumonia.

Franklin Leroy Sterling ⊕ Bowling Green, Ohio; Ohio State University College of Medicine, Columbus, 1914; active member of the staff of Community Hospital; died in the Flower Hospital, Toledo, February 14, aged 59, of coronary occlusion.

Joseph E. Strobel, Waterford, Conn.; Temple University School of Medicine, Philadelphia, 1909; served as superintendent of the Cedarcrest Sanatorium in Hartford from March 1918 to January 1920; had been in charge of tuberculosis treatment at Grasslands Hospital, Valhalla, N. Y.; assistant superintendent of the Seaside, where he died January 30, aged 63, of coronary thrombosis.

Earl Delaskia Tanquary, Fort Scott, Kan.; College of Physicians and Surgeons, Medical Department of Kansas City University, 1901; member of the American Medical Association; served during World War I; died January 31, aged 72, of coronary occlusion.

James Edgar Woods, Atlanta, Ga.; Atlanta Medical College, 1894; served as surgeon for the Southern Railway in Jackson; died February 3, aged 76, of arteriosclerosis.

DIED IN MILITARY SERVICE

Everett Benjamin Archer, Jackson, Tenn.; University of Tennessee College of Medicine, Memphis, 1920; member of the American Medical Association; interned at St. Joseph's Hospital in Memphis; served as resident physician at the Episcopal Eye, Ear and Throat Hospital, Washington, D. C.; formerly associated with the U. S. Public Health Service; at one time on the staffs of the Davis Hospital in Statesville, N. C., McCall Hospital in Rome, Ga., the Trinity Hospital in Little Rock, Ark., and the Veterans Administration Facility in Amarillo, Texas; commissioned a major in the medical corps, Army of the United States, on Feb. 5, 1943; died in the Netherlands January 18, aged 49, of heart disease.

Hira Christopher Baker Jr., Garfield, Ark.; University of Arkansas School of Medicine, Little Rock, 1942; interned at the Pierce County Hospital in Tacoma, Wash.; appointed ensign in the U. S. Naval Reserve on March 24, 1942 and on Dec. 22, 1942 an assistant surgeon with the rank of lieutenant (jg); began active duty on July 10, 1943; on Nov. 1, 1944 appointed lieutenant in the U. S. Naval Reserve for temporary service; died Dec. 18, 1944, aged 28, when his ship, the destroyer U. S. S. *Hull*, foundered in a typhoon.

DeForest Windsor Buckmaster ⊕ Jamestown, N. Y.; University of Michigan Medical School, Ann Arbor, 1921; fellow of the American College of Surgeons; interned at Lutheran Hospital, Fort Wayne, Ind.; chairman of staff, Woman's Christian Association Hospital; member of staff, Jamestown General Hospital; commissioned a major in the medical corps, Army of the United States, on Aug. 20, 1942; died in the Walter Reed General Hospital, Washington, D. C., February 3, aged 47, of carcinoma of the urinary bladder.

William Lyman Fox, Shaker Heights, Ohio; Ohio State University College of Homeopathic Medicine, Columbus, 1917; member of the American Medical Association; served during World War I; commissioned a captain in the medical reserve corps of the U. S. Army on May 27, 1919; later promoted through the ranks to colonel; began active duty on March 1, 1941; recently assigned commanding officer of the regional army hospital at Fort Bragg, N. C.; served as commanding officer of the hospital at Camp McCain, Miss., since his return from the South Pacific; contracted dengue fever in New Guinea, where he was commanding officer of the 134th General Hospital; past president of the Reserve Officers Association of Cleveland; died in Anniston, Ala., February 27, aged 50, of cerebral hemorrhage.

Brooks Collins Grant ⊕ Colonel, M. C., U. S. Army, San Antonio, Texas; Chicago College of Medicine and Surgery, 1915; Army Medical School in Washington in 1920; fellow of the American College of Physicians; served during World War I; appointed a first lieutenant in the medical corps of the U. S. Army Oct. 4, 1919; promoted through the various ranks to that of lieutenant colonel in 1937; later promoted to colonel; had the usual variety of service including a tour of five years (1924-1929) in the Walter Reed General Hospital; in the mobilization prior to the current war was assigned to the command of the 34th Evacuation Hospital at Camp Barkeley, Texas, where he served from July 1941 to January 1942, when he was transferred to the post of Corps Surgeon, 13th Corps, at Providence, R. I., serving until June 1943; went to the European theater in August 1944 but was sent back to Walter Reed Hospital two months later when he became ill; died January 1, aged 54.

Kent Nelson ⊕ Colonel, U. S. Army, retired, Minneapolis; University of Minnesota College of Medicine and Surgery, 1900; Army Medical School in 1901; entered the U. S. Army as an assistant surgeon in 1901; rose through the ranks to that of colonel on June 29, 1927; retired Aug. 31, 1940 but returned to active duty in the same year, when he was reappointed as associate professor of military sciences and tactics and medical ROTC officer at the University of Minnesota, where in 1925 he had been medical ROTC officer and assistant professor of military sciences, serving until 1930; veteran of the Spanish-American War; served in France during World War I; formerly Seventh Corps area surgeon in Omaha; died Nov. 11, 1944, aged 68, of heart disease.

Bureau of Investigation

SECRETS FROM INDIA—VIA DENVER

Victor Croley Plays an Old Game—and Loses

India is a word full of magic. Savants refer frequently to its ancient philosophies and cults; charlatans often pretend that their "secrets" are derived from its lore. They cry their wares with hocus-pocus and mystery.

One Victor A. Croley of Denver, "Consulting Psychologist," also beguiled his fellow humans with such impressive titles as the "Hindu Company" and "Basic Science Fellowship."

Most of the self-anointed "mystics," though supposedly dwelling in a rarer atmosphere than the rest of us, promptly become alert at the mere clink of a coin. Their esoteric existence may be out of this world, but, when necessary, they can be of the earth, earthy. Otherwise Mr. Croley might never have reached the public eye.

Mr. Croley, perhaps no less astute than others who pioneered before him in the field, hit on the idea of "sex rejuvenation." Why not help the longing octogenarian to happiness and fulfilment of desire? Besides, there was money in it. The senile are ready purchasers of promised rejuvenation, with the added aura of Hindu mystery. Ordinary sex books go begging at ten cents or a quarter. A title like "The Hindu Secrets of Virility and Rejuvenation" seems to have been sure fire.

One fine day—according to accounts it was in 1939—Mr. Croley, with perhaps a few associates, who are vaguely hinted at in reports, established himself in the lucrative business of representing to restore to his fellow citizens their "Vim, Vigor and Vitality." Was he not introducing "one of Nature's great secrets"? His books "The Hindu Secrets of Virility and Rejuvenation" and "Feel Vitally Fit," said to be almost identical, were the materials of his business. What hitherto hopeless male, feeling a drab old age creeping on, could resist this appeal in Croley's advertising:

"Men! You can feel years younger. Full of new pep, vim and youthful vigor. Amazing Hindu Secrets stimulate entire system, wipe away the years, restoring former strength and health in many cases. No drugs. No operations. . . ."

"Wipe away the years" carries a stimulating picture. Boy, a towel—and presto! But wait—something still more moving follows. As if further to point a moral and adorn a tale, Croley quotes from an erotic writer of another era, "Frank Harris . . . on Impotency." "If you have tears prepare to shed them now!"—Shakespeare. Mr. Harris, reviewing the moment when he realized his own impotency, thus poured forth his bitter soul:

"Better death than such barrenness of outlook, such a dreadful, monotonous desert. Suddenly some lines came to me:

"'Dear as remembered kisses after death,
Dear as true love and wild with all regret.
Oh death in life! The days that are no more!'"

Here is a form letter from Croley, an astounding albeit depressing revelation of occidental decadence:

"Whereas, among most Americans, impotence and loss of virility is commonplace about age 40, among the Hindus such a condition is unthinkable. Men of 70, 80, 90 and even older retain all the ardor, appetite, strength and lusty vigor of young manhood."

Then why all the ads about impotency in the India press? Mr. Croley continues:

"There are no medicines, no diets. There are no operations; no strange meditative devotions. You do not change your life in any way in using these Hindu secrets, except to include a few daily practices, so simple that after the first two or three days they become a natural part of your daily routine. Furthermore, they exhilarate you from the very first day."

A mere $3.95 and these precious secrets may be yours! You paid your money; in due time the books arrived. The "secrets"—not written in Sanskrit, either—were something of an anticlimax: no esoteric lore here from the ancient Vedas—no references to the occult Upanishads—just a simple set of physical exercises that involve various bending positions of the body in which a tensing and relaxing of the muscles are effected, along with cold baths, certain diets and other elemental hygienic instructions!

No wonder the hard-headed Post Office Department at Washington, which has seen a succession of rosy mail-order promises unfulfilled, was moved to cast a skeptical eye and to undertake an investigation. In due time Mr. Croley was summoned to a hearing at Washington. Why should his little game not be classed as a scheme to defraud and be debarred from the mails? There came a Senior Medical Officer for the Food and Drug Administration to testify for the government and discuss the general classifications of sexual impotence and their causes. Apparently unimpressed by any glamorous claims, he declared that Croley's exercises, similar to ordinary calisthenics, plus Croley's diet and other "hygienic" suggestions, would not restore sexual vigor, overcome psychic factors involved in sexual impotence or provide any means whereby the course of life in the aged can be reversed or the individual restored to the functions of youth. In fact, he attested, to follow Croley's instructions might be harmful or even deadly in some circumstances.

Croley's contention was that the exercises or "movements" described in his book "effect a mild stimulation of the glands, particularly those located in the pelvic girdle, somewhat as a rubber band can be stretched and relaxed," which stimulation, he claimed, "re-activates and restores the glands and so exerts a beneficial effect on the entire system." The medical testimony showed that, though the exercises outlined would produce a general systemic stimulation similar to other calisthenics, they could not accomplish the results that Croley claimed in his advertising.

Instead of a pot of gold at the end of this rainbow, the Post Office Department found only a scheme to obtain money by fraud. An order was entered debarring from the mails the Hindu Company, the Basic Science Fellowship, the Basic Methods Company, "Victor A. Croley, Consulting Psychologist" and plain Victor A. Croley. Too bad, Mr. Croley; it would seem to be a good time to gaze again into the crystal ball!

MISBRANDED PRODUCTS

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the Federal Security Agency

[EDITORIAL NOTE.—These Notices of Judgment are issued under the Food, Drug and Cosmetic Act, and in cases in which they refer to drugs and devices they are designated D.D.N.J. and foods, F.N.J. The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the date of shipment; (4) the composition; (5) the type of nostrum; (6) the reason for the charge of misbranding, and (7) the date of issuance of the Notice of Judgment.]

Allan's Gland Capsules.—Allan & Co., Inc., St. Louis, and John G. Ayars. Shipped between Sept. 18 and Oct. 1, 1941. Composition: essentially extracts of nux vomica and some organic material, with small amounts of arsenic and iodine compounds and zinc phosphide. Adulterated because below standard represented, since it did not contain zinc sulfide. Misbranded because falsely represented as a sexual stimulant and because labeling did not adequately warn against use in cases in which it would be dangerous to health.—[*D. D. N. J., F. D. C. 855; May 1944.*]

Medical Compound for Women.—Primrose R. Devore, trading as Drug Products Company, Columbus, Ohio. Shipped June 18 and Sept. 4, 1941. Composition: essentially extracts of plant drugs, including an alkaloid-bearing drug, sugar and water, preserved with benzoic acid. Misbranded because name falsely represented the product as being efficacious in the cure, mitigation, treatment or prevention of diseases of women.—[*D. D. N. J., F. D. C. 884; May 1944.*]

Mrs. Price's Special Prepared Boric Acid.—Mrs. W. T. Price, trading as Price Compound Company, Minneapolis. Shipped Sept. 16, 1942. Composition not reported. Misbranded because sold under a name recognized in the United States Pharmacopeia, and because purporting to be, and represented as, an antiseptic, and because label failed to give adequate directions for use.—[*D. D. N. J., F. D. C. 857; May 1944.*] Also misbranded under provisions of the law applicable to foods, as reported in *F. N. J. 4489.*

Valtiva.—Harlow B. and Charles E. Boyle, trading as Boyle & Co., Los Angeles. Shipped Nov. 15 and Dec. 9, 1940, and May 12, 1941. Composition not reported. Misbranded because of misleading label representations that product was rich in essential health-building vitamins, and that nervous disorders, skin troubles, loss of appetite and weight, indigestion, constipation, general weakness and ill health are commonly caused by lack of vitamins A, B_1, G and D, which this product contains.—[*D. D. N. J., F. D. C. 762; May 1944.*]

NOMENCLATURE OF EPILEPSY

To the Editor:—A question in Queries and Minor Notes leads me to offer the following points:

The primary manifestations of epilepsy are grand mal, petit mal and psychomotor. These may occur alone or in combination. If the possible combinations are named, four additional diagnoses would be required: grand and petit mal, grand mal and psychomotor, petit mal and psychomotor, and finally grand mal, petit mal and psychomotor. An alternate term for psychomotor is psychic equivalent, which is objectionable because of the implication that this form of seizure is not epilepsy but something like it. The same objection applies to the use of pyknolepsy as an alternate for petit mal. Like narcolepsy and catalepsy, the term pyknolepsy connotes something distinct from epilepsy. This objection is met by using the word pykno epilepsy which also appears in medical dictionaries.

To many physicians and neurologists petit mal means a small or mild seizure of any sort. A separate diagnosis for any disease condition should, however, be based on a difference in character or kind and not simply on a difference of size or degree. A mild scarlet fever is still scarlet fever, a mild grand mal is still grand mal and a mild psychomotor seizure is just that. Petit mal is different from either of these, a transient lapse of consciousness (usually only five to ten seconds long) either without accompanying muscular movements or with only rhythmic jerking (at the rate of three per second) of facial muscles. These minor episodes recur with great frequency (hence the word "pykno," "aggregated"), are relatively innocuous, are most frequent in childhood and adolescence and tend to disappear spontaneously as the person becomes adult. This is exactly what English authors have called pyknolepsy and is better called pykno epilepsy. To avoid present confusion, either the conception of petit mal as a mild seizure of any sort should be abandoned or the term petit mal itself should be dropped and the synonym pykno epilepsy adopted. On electroencephalographic as well as on clinical evidence petit mal is distinct from the two other forms of epilepsy. The pattern made by an alternate sharp dart and smooth dome, recurring approximately three per second, which always accompanies petit mal, is distinctive, probably diagnostic, of this variety of epileptic seizure. This form of seizure discharge is rarely encountered in so-called symptomatic (acquired) epilepsy.

Petit mal (pykno epilepsy) is the purest and most frequent expression of essential (genetic) epilepsy.

WILLIAM G. LENNOX, M.D., Boston.

ORAL PENICILLIN

To the Editor:—The view is generally held that penicillin is inactivated by the acid of the stomach (Rammelkamp, C. H., and Keefer, C. S.: The Absorption, Excretion and Distribution of Penicillin, *J. Clin. Investigation* **22**:425 [May] 1943) and that the drug cannot be effectively administered by the oral route unless it is given in combination with buffers (György, Paul; Vandegrift, H. N.; Elias, William; Colio, L. G.; Barry, F. M., and Pilcher, J. D.: Administration of Penicillin by Mouth, THE JOURNAL, March 17, p. 639) or in peanut oil (Libby, R. L.: Oral Administration of Penicillin in Oil, *Science* **101**:178 [Feb. 16] 1945). A simple and, as judged by clinical response, effective method of administering penicillin by mouth in my experience has been to make up 100,000 units in only 5 cc. of saline solution and then give 20,000 or 40,000 units as an oral dose of 1 or 2 cc. The administration of the dose in the relatively small volume is not irritating and apparently permits absorption of the drug in the mouth, pharynx and esophagus without the possibility of inactivation by the acid gastric juice.

CAMPBELL MOSES, M.D.
University of Pittsburgh School of Medicine.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Regulation Requiring Applicant to Present Transcript of School Record Unreasonable as Applied to Graduate of German School.—So far as is here material, the Illinois medical practice act provides that an applicant for examination for a license to practice medicine in all its branches, if a graduate of a medical college prior to June 3, 1923, must (1) have graduated from a medical college that as a prerequisite to graduation required a four year course of instruction of not less than nine months each and that was reputable and in good standing in the judgment of the Department of Registration and Education and (2) have completed a four year course of instruction in high school or its equivalent. (Ill. Rev. Stat. 1943, ch. 91, sec. 4.) Before being examined an applicant must submit evidence under oath to that effect satisfactory to the department (*ibid.*, sec. 2). The department by regulation requires applicants "to submit complete transcripts of medical and premedical records with applications." Schutz, a naturalized citizen of German birth, after preliminary studies in various secondary schools in Germany, pursued medical studies in several German universities from April 1906 to Jan. 15, 1912, graduating from the University of Munich on the latter date. After examination he was licensed as a physician in Germany, March 19, 1913. He was awarded an M.D. degree by the University of Breslau in 1917. In 1938 he was deprived of his license to practice in Germany solely, he alleged, "because he was a non-Aryan" and emigrated to the United States. Subsequently he sought a license to practice medicine in Illinois. Apparently while it was admitted that the schools attended and the studies pursued in Germany by Schutz were sufficient in quality and quantity to comply with the minimum requirements of the Illinois act, he was denied the right to be examined for a license because he could not comply with the rule of the department requiring the presentation of complete transcripts of medical and premedical school records. Apparently when Schutz emigrated from Germany the transcripts of his grades were confiscated by the Gestapo and it was impossible for him to secure copies of them because of that fact and because of the further fact that at the time of the application Germany was an enemy country and in any event would not permit the furnishing of any such copy of records for a non-Aryan. Schutz instituted mandamus proceedings against the director of the Department of Registration and Examination and against its superintendent to compel them to examine him. From an adverse judgment the departmental officials noted appealed to the appellate court of Illinois, first district, second division.

The question here presented, said the appellate court, is whether or not, in the light of the circumstances stated, the regulation of the department requiring applicants to submit transcripts of medical and premedical records is reasonable in its general terms and intent and, if not, whether or not mandamus will lie to compel the department to consider other competent evidence of the applicant's qualifications to be admitted to the examination. The rule is well settled that courts may review the regulations of the department of registration and education to determine whether they are fair, reasonable and impartial. The medical practice act as it relates to the appli-

cation of Schutz, who graduated from a medical school prior to June 3, 1923, provides that at the time of graduation the medical college from which he graduated must have required as a prerequisite to graduation a four year course of instruction and that the college must have been reputable and in good standing in the judgment of the department. The medical practice act specifies the number of months' school attendance required and the minimum time of the school course and prescribes minimum standards of professional education to be enforced by the department. A rule of the department provides that proof of the completion of a course of studies in a medical school and graduation therefrom shall be evidenced by a diploma which shall be submitted to the department by the applicant. Schutz completed studies at medical colleges and high schools for periods in excess of those required by the act and received diplomas which he delivered to the department. The act further requires that the applicant must be a graduate of a medical school which is reputable and in good standing in the judgment of the department. From the record before us it must be assumed that the colleges attended by Schutz were reputable and in good standing in the judgment of the department. The rule of the department provides that a diploma from such college shall evidence the fact of graduation. Thus, Schutz complied with the statutory provisions and with the rule of the department prescribing what might serve to evidence the fact of graduation. The appellants conceded that "the court may take judicial notice of the facts of current history"; that, "due to the tragic convulsions of Europe, many exiles from that unhappy continent have found asylum within the shores of the United States," and that "undoubtedly many of these refugees possess professional or other technological skill which could be exploited to the advantage of the people of the state of Illinois." Nevertheless the appellants contended that, since there are others whose lack of qualifications is such that to permit them to hold licenses to practice medicine would be highly dangerous, the department has long insisted that all candidates to practice must present certain specific credentials, which include a showing of the courses pursued in the institutions of higher learning, to be certified and authenticated by the institutions themselves and not otherwise. But, answered the appellate court, the primary purpose of the medical practice act is to safeguard the public health by prescribing standards for those who shall be permitted to treat human ailments, and the department was created to determine in the first instance whether the applicant has submitted satisfactory evidence that "he has the preliminary and professional education required by this act" (medical practice act, sec. 4) and, if so, to admit him to the examination and issue a license if he passes successfully. The proof required by the departmental regulation under discussion goes to the form rather than to the substance of the evidence submitted by the applicant as to his educational qualifications, and, if an applicant can satisfy the department as to his qualifications by other satisfactory evidence, the department should be required to consider it and not arbitrarily insist on documents which admittedly cannot be produced. Under the "best evidence rule" the highest degree of proof of which the case from its nature is susceptible must, if accessible, be produced; but where the evidence offered, while not of the highest degree or of the most satisfactory kind, is otherwise competent and is the best evidence which under the circumstances can be produced, and the absence of evidence of a higher degree or of a more conclusive character is not attributable to the fault of the party seeking to prove the fact in controversy, then the requirements of the best evidence rule are complied with and the evidence is admissible. *32* C. J. S., Evidence, sec. *777*, 779, p. 701 et seq. For the department to insist on a regulation, without regard to the circumstances, which is more exacting than the commonly accepted rules of evidence under which courts operate daily is an arbitrary and unreasonable requirement.

The judgment in favor of Schutz was accordingly affirmed.—*People ex rel. Schutz v. Thompson, 59 N. E. (2d) 494 (Ill., 1945).*

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, April 28, page 1148.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 26-28. Sec., Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

ALASKA: Juneau, September. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

ARIZONA:* Phoenix, July 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS:* *Eclectic.* Little Rock, June 7. Sec., Dr. C. H. Young, 1415 Main St., Little Rock. *Medical.* Little Rock, June 7-8. Sec., Dr. D. L. Owens, 701 Main St., Little Rock.

CALIFORNIA: *Oral.* San Francisco, May 20. *Written.* San Francisco, July 9-12. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

COLORADO:* Denver, July 3-7. Final date for filing application is June 18. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT:* *Homeopathic.* New Haven, July 10-11. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven. *Medical. Examination.* New Haven, July 10-11. *Endorsement.* New Haven, July 24. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: *Examination.* Dover, July 10-12. *Reciprocity.* Dover, July 17. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA:* *Reciprocity.* Washington, June 11. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA:* Jacksonville, June 25-26. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.

IDAHO: Boise, July 10. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, June 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, Aug. 28-30. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

KANSAS: Kansas City, June 28-29. Sec., Board of Medical Registration & Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

KENTUCKY: Louisville, June 18-20. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

LOUISIANA: June. Sec., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans 12.

MARYLAND: *Medical.* Baltimore, June 19-22. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 19-20. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, July 10-13. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F. State House, Boston.

MICHIGAN:* Detroit, June 26-28. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

MINNESOTA:* Minneapolis, June 19-21. Sec., Dr. J. F. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSISSIPPI: Jackson, June 25-26. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

MISSOURI: St. Louis, June 7-9. Sec., State Board of Health, Miss Erma E. Nixon, State Capitol Bldg., Jefferson City.

MONTANA: Helena. Oct. 1-3. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEVADA: Carson City, May 7. Sec., Dr. G. H. Ross, 215 N. Carson St., Carson City.

NEW JERSEY: Trenton, June 19-20. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NORTH DAKOTA: Grand Forks, July 3. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OHIO: *Endorsement.* Columbus, July. *Examination.* Columbus, June 18-21. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA:* Oklahoma City, June 14-16. Sec., Dr. J. D. Osborn, Jr., Frederick.

SOUTH CAROLINA: Columbia, June 25-27. Sec., Dr. N. B. Heyward, 1329 Blandina St., Columbia.

SOUTH DAKOTA:* Pierre, July 17-18. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, State Capitol, Pierre.

TEXAS: Galveston, June 4-6. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

VERMONT: Burlington, June. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA:* Richmond, June 20-23. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WASHINGTON:* Seattle, July 16-18. Sec., Department of Licenses, Miss Nell Adams, Olympia.

WEST VIRGINIA: Charleston, July 5-7. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

WISCONSIN:* Milwaukee, June 26-28. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING: Cheyenne, June 4-5. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, June 6-7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: June 9. Address State Board of Healing Arts, 250 Church St., New Haven 10.

FLORIDA: DeLand, June 1. Final date for filing application is May 17. Sec., Dr. J. F. Conn, John B. Stetson University, DeLand.

MICHIGAN: Ann Arbor and Detroit, May 11-12. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.

NEW MEXICO: Santa Fe. May 6-7. Sec., Miss Marion M. Rhea, State Capitol, Santa Fe.

OREGON: Portland, July 7. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.

RHODE ISLAND: Providence, May 16. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.

SOUTH DAKOTA: Yankton, June 19. Sec., Dr. G. M. Evans, Yankton.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Ophthalmology, Cincinnati

28:123-242 (Feb.) 1945. Partial Index

Rubeosis Iridis Diabetica. F. B. Fralick.—p. 123.
Ophthalmoscopy and Diagnosis of Human Illness. A. J. Bedell.—p. 139.
Discussion of Ocular Malingering in Armed Services. A. C. Unsworth.—p. 148.
Patron Saints of Eyes: Outline. F. L. P. Koch.—p. 160.
Ocular Therapy with Penicillin Used Topically, Intraocularly and Systemically. C. A. Mietus.—p. 173.
Serologic Studies in Acute Eye Diseases. C. C. Gray and W. A. Moor.—p. 180.
Intraocular Injection of Penicillin in Ocular Infections. V. La Rocca.—p. 183.
*Congenital Cataract Following Rubella in Mother. C. A. Perera.—p. 186.
Chemotherapy in Treatment of Sympathetic Ophthalmia. A. E. Long.—p. 187.
Trichoepithelioma of Eyelid. J. E. L. Keyes.—p. 189.
Endophthalmitis Subsiding After Treatment with Penicillin. M. I. Green.—p. 191.
Luxation of Lens with Voluntary Control. O. R. Wolfe.—p. 193.
Report of Eye Injured By Lightning. L. B. Sheppard.—p. 195.

Congenital Cataract Following Rubella in Mother.—Perera directs attention to the occurrence of congenital cataract and other congenital anomalies in children born of mothers who have rubella during the first three months of pregnancy. A girl aged 4½ months was referred to him in April 1944 because of a white pupil of the right eye. The baby was born at term but at the age of 8 weeks weighed no more than at birth (6¼ pounds, or 2,840 Gm.). She had rickets and scurvy, and a spontaneous hemorrhage into her left knee joint, with subsequent abscess formation. Her parents and her 5 year old sister had "German measles" when her mother was in her second month of pregnancy. Physical examination revealed a dense central cataract of the right eye, a congenital cardiac condition (probably patent ductus arteriosus) and malnutrition.

Archives of Otolaryngology, Chicago

41:99-160 (Feb.) 1945

Osteoma of Frontal Sinus: Report of 5 Cases. J. R. Dowling.—p. 99.
Penicillin in Acute Otitis Media and Mastoiditis: Report of Case. S. Ball.—p. 109.
Ménière's Disease. R. F. Mogan and C. J. Baumgartner.—p. 113.
Thrombophlebitis of Lateral Sinus. H. Rosenwasser.—p. 117.
*Local Use of Sulfonamide Compounds in Surgical Treatment of Ear. F. W. Merica.—p. 133.
Rational Therapy in Acute Otitis Media. J. P. Rigg.—p. 137.
Importance of Pathologic Conditions of Nasopharnx to Otolaryngologist. O. R. Kline.—p. 140.
Diabetic Gangrene Involving Sinuses. B. R. Dysart.—p. 143.
Chronic Progressive Deafness, Including Otosclerosis and Diseases of Inner Ear. G. E. Shambaugh Jr. and M. H. Cutler.—p. 147.

Local Use of Sulfonamides in Surgery of Ear.—Merica thinks that the downward trend of disease of the mastoid process requiring mastoidectomy apparently can be attributed to the systemic use of chemotherapy in combating acute infections. A survey of the records in three Cleveland hospitals showed that there were 153 cases in 1937 in which mastoidectomy was performed, 134 in 1938, 121 in 1939, 79 in 1940, 82 in 1941, 65 in 1942 and 35 in 1943. Thus cases in which mastoiditis required surgical intervention have been reduced to almost one fifth in six years. Sulfanilamide powder lightly insufflated into the auditory canal after myringotomy shortens the period of drainage and helps to prevent local irritation of the canal. Chronic furunculosis of the auditory canal responds rapidly to the local use of a 5 or 10 per cent sulfathiazole ointment. During the last two and a half years the author has made it a routine practice to use sulfanilamide powder locally in ears with chronic otitis media. The type and the location of the perforation of the tympanic membrane influence the results. In the ears most amenable to treatment there usually is a large, centrally situated perforation. Ears in which there is a marginal or an attic perforation, usually small, with a foul thin purulent discharge and evidence of cholesteatomatous or other débris are much more resistant to treatment. The local use of sulfonamide compounds has greatly shortened the postoperative course after simple mastoidectomy. The author believes that it is justifiable to close a simple mastoidectomy wound completely after local use of sulfanilamide. The action of the drug and the purpose for which it is used are frustrated if a drain is used. If there is no sudden unexplained rise in temperature, the dressing should be left four to six days without changing. Contamination in such wounds is always introduced from the outside. There is some difference of opinion as to the best drug to use, but sulfanilamide is probably preferable among those now available.

Blood Vessels in Fat Tissue: Relation to Problems of Gas Exchange. I. Gersh and Mary A. Still.—p. 219.

Virus Neutralizing Action of Serum from Mice Infected with Poliomyelitis Virus.—Brown and Francis present evidence that the serum of mice paralyzed with the Lansing strain of poliomyelitis virus possesses the capacity to protect normal mice against the same virus when mixtures of virus and serum are inoculated intracerebrally. The virus neutralizing action was present mainly in mice paralyzed between the third and sixth days following inoculation and was rarely demonstrable in the serum of mice developing paralysis more than ten days after inoculation. Serum from nonparalyzed mice had approximately the same neutralizing capacity when obtained during the same period following inoculation in which serum from paralyzed mice showed the greatest effect. Neutralization of the virus was not obtained with serum from normal mice or from mice inoculated with normal nervous tissue.

*Diagnosis and Treatment of Tumors of Testis. C. A. Hellwig.—p. 37.
Aspiration Pneumonia with Beginning Lung Abscess Treated with Penicillin. R. R. Snook.—p. 40.
Tuberculous Gingivitis, with Report of Case. E. W. Johnson Jr.—p. 42.

Tumors of Testis.—Hellwig states that of 254 specimens received at his laboratory with the clinical diagnosis tumor of the testis 50 proved to be of a malignant nature. He thinks that any noninflammatory mass of the testis should be considered as a malignant neoplasm until proved otherwise. The preoperative diagnosis of malignant tumors of the testis is often impossible. Aspiration biopsy is uncertain and diagnostic palpation of the tumor should be done as gently as possible. The diagnostic value of the Aschheim-Zondek test is limited. A positive test may be the only evidence of the disease; a negative test does not rule out cancer. The value of preoperative x-ray treatment has not been established and the effect of postoperative irradiation is not sensational. The most important factor in determining the prognosis is the absence or presence of metastasis at the time of orchiectomy. As long as the tumor is confined to the testis itself there is an excellent chance of complete cure.

Maxillofacial Injuries. G. W. Christiansen.—p. 76.

Diabetes Tomorrow.—Joslin and his associates think that a consideration of the future for diabetes must be based on the startling increase in the number of persons with diabetes in the population. Three causative factors are evident: (1) more intensive search for and discovery of cases by better methods, (2) the aging of the population and (3) the prolongation of diabetic lives as the result of better treatment. Formerly diabetes beginning before the age of 15 years was fatal in less than two years. Now with insulin such patients live long. Actually among 1,657 children seen and treatment begun since the discovery of insulin in 1922 only 137 have died. In the first seven years of this period 82 per cent of the deaths were due to diabetic coma, whereas the incidence of deaths in the last few years has fallen to only 18 per cent. Diabetic coma is preventable, but it continues to be a major cause of death. An analysis of 601 coma cases treated at the New England Deaconess Hospital between 1923 and 1944 has convinced the authors that it is the amount of insulin given in the first three hours of treatment which is of primary importance in determining the recovery or the death of the patient. Among 478 patients in coma treated from 1923 to 1940, 12 per cent died. When the insulin given in the first three hours of treatment was increased from 83 units to an average of 216 units among 123 consecutive cases treated between August 1940 and May 1, 1944 the mortality was only 1.6 per cent. Important aids in treatment are (*a*) the use of isotonic solution of sodium chloride intravenously or subcutaneously (4,000 cc.) or, when necessary to overcome shock and impending anuria, up to 10 per cent or even 15 per cent of body weight and (*b*) gastric lavage. The administration of glucose is harmful in diabetic coma. There has been improvement in the treatment of juvenile and pregnant diabetic patients.

Treatment of Sprains with Ethyl Chloride Spray.—Treatment of sprains and minor injuries in which the skin is not broken, by means of surface anesthesia combined with active motion, is an effective method of therapy. The ethyl chloride spray is more advantageous than injection of procaine hydrochloride. The technic is simpler and requires no special instruments, sterilization or special surgical skill. There are no systemic after-effects and no danger of introducing infection into the injured area from the needle or skin. Large painful areas can be treated. The one possible complication is frostbite, which can be prevented by application of camphor liniment to the skin after spraying. A mild reactive hyperemia seems to improve the local circulation and is followed by a decrease in the swelling of the joint. The patients secure symptomatic relief and a return of useful function to the injured part. The immediate recovery varies from 60 to 90 per cent, depending on the severity and duration of the injury. Disability averages less than three days. No strapping with adhesive tape or the application of plaster casts is required. The treatment will not mask fractures, severe deep tissue injury or disease. In this respect it is superior to the injection of a local anesthetic. The treatment is simple and not expensive, and disability and hospitalization are reduced.

Food Poisoning. G. H. Hauser.—p. 362.

Rocky Mountain Spotted Fever.—According to Pullen and his associates 145 cases of endemic (murine) typhus were observed in a ten year period at Charity Hospital in New Orleans and only 1 case of Rocky Mountain spotted fever. The pathologic changes in the two diseases are essentially the same, consisting of an acute endangiitis of the small blood vessels throughout the body, particularly in the brain and skin. In Rocky Mountain spotted fever there is usually a more severe lesion in the vessels and a greater enlargement of the spleen, as well as a greater tendency to gangrene. In spotted fever the rickettsias invade the smooth muscles of the media of the blood vessels, in typhus the endothelium. Hence thrombotic lesions in spotted fever are generally more severe than in typhus fever, and necrosis of fingers, toes, face, ears, scrotum and vulva may occur. The rash of spotted fever appears earlier in the illness, often within twenty-four to forty-eight hours after the onset, and it is usually more hemorrhagic and purpuric in nature. The rash of spotted fever tends to appear first on the back, wrist and ankles, with early involvement of the palms of the hands and soles of the feet. Later the forehead, arms, legs, chest and abdomen are affected. In endemic typhus the rash usually appears first on the chest and upper part of the abdomen, and involvement of the face, wrists, ankles, palms and soles rarely occurs. Neither the nature of the lesions nor their localization can be relied on absolutely for differentiation. The diagnosis must be based on laboratory evidence, such as the specific complement fixation test, skin biopsies, animal inoculations and cross immunity tests, and protection tests. It is not unlikely that more instances of this disease will be found if the disease is considered in the differential diagnosis of acute infectious diseases with exanthematous manifestations, and specimens of blood are sent to diagnostic centers for study.

Cultivation of Mumps Virus in Developing Chick Embryo and Its Application to Studies of Immunity to Mumps in Man. K. Habel. —p. 201

Antibiotic Substance Similar to Penicillin in Pathogenic Fungi.—Peck and Hewitt state that the occurrence of antibiotic substances has been noted previously in only one species of pathogenic fungi, namely Aspergillus fumigatus. They investigated a number of fungi for the existence of antibiotic substances. A strain of Trichophyton mentagrophytes which was isolated from the arm of a patient presenting a clinical case of dermatophytosis was found to produce an antibiotic substance. This fungus was used for most of the experiments. A survey was made to determine how uniformly the ability to produce an antibiotic factor occurred among other dermatophytes. Several members of the group of fungi occurring in clinical lesions of dermatophytosis were found to elaborate a factor antagonistic to certain other micro-organisms. This factor appeared to be similar to penicillin in the following respects: (*a*) enhanced production on mediums containing corn-steep liquor, (*b*) spectrum of activity and behavior toward penicillin resistant organisms, (*c*) sensitivity to p_H and temperature and (*d*) destruction by clarase.

Endometriosis of Bladder and Ureter.—A review of the subject of endometrial invasion of the bladder and ureter by O'Conor and Greenhill suggests that, while these cases are probably rare, they are more common than the literature would indicate. Vesical endometriosis seems to be always secondary to pelvic endometriosis that has extended into the bladder from affected contiguous organs. Only 58 authentic instances have been recorded. The authors report 2 cases that they observed. Subjective bladder symptoms are variable. Cyclic disturbance was recorded in only two thirds of the patients. The most constant symptom seems to be a sense of pressure or weighty discomfort in the vesicovaginal region. The cystoscopic appearance of endometriosis of the bladder may or may not be similar to the appearance of a "chocolate cyst" of the ovary. In many instances the mucosal changes have been reported as cyclic in character. In other instances the appearance is not unlike that of a chronic inflammatory lesion or an early area of infiltrating carcinoma. In the described case with vesical endometriosis the cystoscopic appearance of the lesion was so typical as to leave no doubt as to the cellular nature of the invasion. Removal of the ovaries or the arrest of their function usually causes an abrupt ending of the disease. Occasionally removal of the ovaries does not arrest the disease. In younger women, in whom one should make an effort to preserve as much ovarian tissue as possible, localized excisions of involved areas should be practiced. Unfortunately, in these patients recurrences are not uncommon and further surgery may be necessary. The second case reported here is noteworthy because it was one of intraureteral endometriosis, only 1 other case of this type having been reported before. The patient, a woman aged 50, recovered

following removal of the ureter and kidney. The authors emphasize the importance of recognizing vesical and ureteral endometriosis in the differential consideration of tumors of the bladder and ureter.

Androgen Control in Carcinoma of Prostate.—Herger and Sauer employed castration singly or in combination with diethylstilbestrol medication in treating patients with demonstrable metastasis or with rapidly progressing lesions. Exclusive administration of diethylstilbestrol, usually in doses of 1 mg. daily, was reserved for patients with low grade malignant tumors with no demonstrable metastasis, in whom little progression was anticipated. Diethylstilbestrol alone was given also to patients who refused or who were unsuitable for orchiectomy. Obstructive symptoms were treated by the usual methods, such as the indwelling catheter, suprapubic cystostomy or transurethral resection. Orchiectomy alone was carried out on 26 patients, 19 of whom had metastasis. In 48 other patients, 35 of whom had metastasis, castration was either preceded or followed by administration of diethylstilbestrol. The remaining 56 patients received exclusive diethylstilbestrol medication; metastasis was found in 11 of these cases. Analyzing the results obtained in their 130 cases, the authors say that favorable response was accomplished in numerous instances. Prolonged observation revealed that in a considerable number initial improvement developed into delayed failures. Even the most spectacular improvement has to be viewed with skepticism as to the ultimate outcome. Androgen control treatment has prolonged the lives of patients with far advanced or metastatic disease. The response to this treatment is much more impressive than the poor results accomplished by external or interstitial irradiation. Although improvement is of temporary duration, the simplicity of the method and the low surgical risk involved justify its use in combination with the usual methods in the treatment of high grade urinary obstruction. The results were most favorable in cases of metastatic lymph node involvement. Spread or local extension of bone metastasis is not arrested by androgen control treatment. Furthermore, this treatment does not protect the patient with nonmetastatic cancer of the prostate from developing metastasis at a future time. In spite of the apparent ineffectiveness of androgen control therapy on the bone metastasis, it cannot be denied that many of these patients derive temporary benefit, such as disappearance or improvement of pain, gain in weight and increase in well-being. Androgen control treatment, and particularly orchiectomy, should not be carried out indiscriminately in all cases of carcinoma of the prostate. Castration should be reserved for patients with metastatic disease, patients in whom metastasis is suspected or patients with rapid enlargement of the primary lesion.

Hemorrhagic Shock: Effect of Amino Acids, Amigen and Gelatin in Dogs.—A comparison of the values of saline solution, red blood cell saline suspension and heparinized plasma in the treatment of hemorrhagic shock in dogs produced by an easily standardized method has been recently reported from the laboratory of Nicholl and his collaborators, who report a continuation of the work with comparative tests of pure crystalline amino acids, an enzymatic hydrolysate of casein (amigen) and bone gelatin. They stress the following points: 1. Under the conditions of these experiments an amino acid (10 per cent) solution and a solution (10 per cent) of a hydrolysate of casein and pork pancreas (amigen) were found to be ineffective in overcoming shock produced by a severe acute hemorrhage in each of 7 dogs. 2. Under the same conditions suspensions of red cells in solutions of amino acids and amigen proved more effective than amino acid or amigen solutions without red cells and less effective than the gelatin used in treating this type of hemorrhagic shock. 3. Under similar conditions 3 per cent solutions of bovine bone gelatin which had previously been autoclaved twenty minutes and one hundred and eighty minutes proved 100 per cent effective in overcoming hemorrhagic shock in 15 dogs. 4. The apparent ability of this gelatin to maintain circulatory volume without untoward reaction supports its careful trial in the emergency treatment of hemorrhagic shock in human beings.

Treatment of Infiltrating Carcinoma of Urinary Bladder.—Wayman and Marting present a new method of interstitial irradiation for carcinoma of the bladder which they believe offers a technic by which sterilizing doses of radiation may be applied to bladder tumors without injury to the surrounding tissues. In employing this method it is important to determine whether the tumor mass is situated in the base of the bladder or at some other location so that the proper exposure of the bladder may be utilized. If the tumor is located on the trigone and can be palpated through the vagina or rectum the bladder is exposed by using the vaginal or the perineal approach. If the tumor is located in a position other than the trigone the suprapubic approach is employed. The authors describe and illustrate these different methods of approach. The total dose of radium applied by the authors with this interstitial method of treatment was 4,341 to 7,320 millicurie hours. They show that if the needles are placed approximately 1 cm. apart throughout the entire tumor-bearing area all of the malignant cells will receive the minimum lethal dose. The needles should be placed parallel to one another so that they do not crisscross and produce overconcentration of radiation at any single point. This method is applicable in inoperable as well as in operable bladder tumors.

Fibrositis and Reality. M. Kelly.—p. 46.

Experimental Transmission of Rheumatic Fever.—Copeman obtained adult volunteers for an experiment on transmission of rheumatic fever. From a patient who had a typical attack of rheumatic fever he obtained blood on the fourth day of his illness and transferred it to 5 volunteers. The blood of 2 who showed a rheumatic reaction was then taken and injected into a further group of volunteers, and so on. It was only in the fourth "generation" of volunteers that no further reaction of any sort was noted. The author thinks that it might be surmised from this experiment (1) that rheumatic fever can be transmitted in the blood of an active sufferer and (2) that the syndrome of rheumatic fever may be a synthesis of two elements: (*a*) a febrile nonspecific element and (*b*) a specific fibrotoxic (and cardiotoxic) element, since it seemed that there was some clinical evidence of these two elements developing independently in certain of the volunteers.

Crystalline Penicidin.—Atkinson and her collaborators state that, as a result of further work on production and purification, penicidin has now been prepared in crystalline form. A method resembling that described by Birkinstraw and his associates was adopted for the extraction of penicidin. The final yield of crystalline penicidin was disappointingly small. Penicidin was actively antiluminescent; it shared this characteristic with other antibacterial substances produced by molds, notably aspergillic acid. Jones et al. found the antiluminescence titration satisfactory for assaying solutions of aspergillic acid; the authors have found it useful in estimating the concentration of penicidin in crude and partially purified preparations. So far only biologic methods have been successful in detecting and estimating penicidin, and of the available methods the antiluminescence titration provides results in the shortest time.

Pulmonary Disease in Graphite Workers.—The observations reported by Dunner were made during routine examinations of 5 men who had been working with graphite for many years. The graphite when removed from its containers gives rise to a dust which is inhaled for many hours daily. The men had handled graphite for from seventeen to thirty-four years. Physical examination by percussion and auscultation revealed slight changes, but the mild symptoms and few physical signs are in striking contrast to the x-ray appearances. The first patient, a man aged 56 who had worked with graphite for twenty years, had had cough and sputum for many years and recently pains in the chest. The x-rays revealed patchy infiltration throughout the right lung. Nodular opacities could be distinguished. The infiltration became more homogeneous at the base. There was slight patchy infiltration at the left base. The second patient had cough and sputum but felt well. Another patient was troubled with bronchitis, which caused him to be absent from work occasionally. The 2 other men had no complaints. The chest roentgenograms of all 5 showed opacities, reticulation, nodulation and other changes. The author concludes that graphite dust can produce pneumonoconiosis. The symptoms are mild even in advanced cases, and diagnosis must be based on x-ray examination.

Scabies Prophylaxis Using "Tetmosol" Soap.—A soap has been produced which contains 10 per cent of "tetmosol" (tetraethylthiuram monosulfide). The use of this soap has been shown to kill Sarcoptes and thus to cure scabies, though as a therapeutic agent at a treatment center it is less efficient than benzyl benzoate. It is, however, so simple to use that it seemed possible that its general issue to an infected population would prevent further transmission of the disease. Patients in a mental hospital used tetmosol soap for a period of eleven weeks. Scabies, which was very prevalent at the start of the experiment, was almost entirely eliminated. Most cases were cured, and the spread of the disease was prevented.

Action of Penicillin on Bacteria.—Garrod says that penicillin is fairly rapidly lethal to susceptible bacteria. All commercial penicillins tested were less active in high than in low concentrations. Impurities which presumably cause this and

other anomalies present a serious problem. Nothing is likely to be gained by using high concentrations, particularly for local treatment. A concentration of 1 unit per cubic centimeter is not only just as effective as one of 1,000 units but often more so. The only good reason for using strong solutions in local treatment is to ensure that loss by escape, dilution or absorption shall not permit the concentration to fall below the minimum level for full effect, which may be about 0.1 unit per cubic centimeter. The factors controlling this loss vary almost infinitely, from good retention in a closed space to the impossibility of retention and the dilution by copious exudate which characterizes some open wounds. The optimum strength of solution must therefore vary, but the standard probably need not exceed 250 units per cubic centimeter. These experiments also have some practical bearing in relation to Bigger's proposal that systemic penicillin treatment should be intermittent. His argument is that penicillin kills only dividing cells and that a small proportion of dormant nondividing cells, which he terms "persisters," are liable to survive; these must be permitted to grow by interrupting treatment if sterilization is to be complete. Studies of the effect of temperature and particularly of reproductive activity on susceptibility to penicillin demonstrate behavior which seems to differ in no qualitative sense from that of other disinfectants.

Temporary "Fastness" of Staphylococci to Penicillin.—Two strains of coagulase positive staphylococci were made penicillin "fast" by cultivation in increasing quantities of penicillin. They were then subcultured daily in broth without penicillin and, contrary to expectations, a rapid fall in resistance to penicillin was noted. It therefore appears that "fastness" of staphylococci to penicillin is not a permanent characteristic but that staphylococci which have become resistant to penicillin in vivo might similarly revert to the penicillin sensitive state on withdrawal of the drug. Indeed, it seems possible that the reversion might be more rapid in vivo than in vitro.

Metazoan Immunity. D. B. Blacklock.—p. 84.

Bacteriolytic Action of Penicillin.—Todd investigated a number of organisms for their susceptibility to bacteriolysis by penicillin. He found that all the penicillin sensitive organisms tested were susceptible to bacteriolysis by penicillin. Penicillin insensitive organisms, such as Escherichia coli and Pseudomonas aeruginosa, were not lysed by penicillin. The question arises whether the bacteriostatic action of penicillin is separate from the bacteriolytic action or whether they are different manifestations of the same process. There can be no doubt that penicillin is capable of killing micro-organisms without lysis, and it seems probable that multiplications, death and lysis may all occur independently at the same time in a culture containing penicillin. This was observed in a culture in which during the first two hours of incubation turbidity increased with a diminishing colony count, presumably owing to rapid multiplication accompanied by a still more rapid death rate but without correspondingly rapid lysis. After this initial period, progressive lysis and a steadily falling colony count proceeded to complete lysis and complete sterilization. When the potential rate of multiplication is increased by the addition of serum, bacteriolysis begins within an hour without preliminary increase of turbidity or other evidence of multiplication. It is, however, possible that in this case multiplication is not detectable because both the death rate and the rate of lysis exceed the rate of multiplication. It seems to be a general rule that the rate of bacteriolysis by penicillin depends on the actual or potential rate of multiplication of the organisms. Staphylococci which are not actively dividing survive in penicillin, while the actively multiplying organisms are killed. It may be that the real reason why penicillin is so effective is that young cultures in the stage of active multiplication are more susceptible to the bacteriolytic action of penicillin than older cultures. It is therefore fortunate that the organisms which are in such a state that they could readily invade the human body are in just the state in which they are most susceptible to the bacteriolytic action of penicillin.

Sulfamezathine in Pneumococcic Pneumonia.—Ramsay and his associates report that sulfamezathine has been used in the treatment of a further 287 cases of pneumococcic lobar pneumonia with a case fatality rate of 8.4 per cent. Of the 24 patients who died, 22 were over 50 years of age. It is confirmed that the drug is relatively nontoxic and that the number of complications is not high. An analysis of the deaths in this and in the previous series suggests the following points as an aid in reducing still further the mortality of lobar pneumonia: Steps must be taken to ensure an adequate drug concentration in the blood in the first twenty-four hours in severely toxic cases and in those coming for treatment after the seventh day of the disease. In older patients the heart condition should be assessed and adequate convalescence allowed. Abdominal symptoms should be regarded as a sign of toxemia and receive early treatment. An undetected empyema may be one of the reasons for the development of pneumococcic endocarditis.

Louse Borne Typhus Fever.—Stevens says that, during the first six months of 1943, 21 cases of louse borne typhus fever were admitted to a military hospital in the Middle East. Seven of them were treated with hyperimmune rabbit serum prepared by the Lederle Laboratories of New York and supplied by the U. S. Army medical services. Six patients were given large doses of serum as soon as clinical diagnosis was established and all recovered. A seventh patient, given a smaller dose, died. No attempt is made to draw conclusions from so small a series. The serum apparently has a beneficial effect by modifying the severity of the course and reducing the toxemia. Emphasis is placed on giving the serum as early as possible and in adequate dosage.

Some Methods of Nonskeletal Traction. M. C. Wilkinson.—p. 78.

Excision of Proximal Row of Carpus.—Stamm states that the object of treatment must be to restore a free range of movement, throughout which no structures are submitted to excessive stretching or impaction. The essential step in any arthroplasty is to provide a gap whose closure will relax the surrounding structures and so relieve the tissues from stress. The removal of one bone or part of one bone from the proximal row of the carpus does not affect this relaxation. Excision of the whole of the proximal row of the carpus offers a possible solution. It not only provides a good joint gap but also results in the substitution of a simple ball and socket joint between the os capitatum and the radius for the normal complicated link-joint mechanism. The operation requires care so as not to damage the radius or other carpal bones. The after-treatment is all important. The final result cannot be expected in less than four months. The average result is a wrist with 50 to 70 per cent of the normal range of movement, slight weakness of grip and occasionally some degree of pain on forced radial deviation of the wrist. Even if arthrodesis should ultimately prove necessary, it will have been greatly facilitated by the removal of the proximal row of the carpus.

*Amphetamine Sulfate Therapy of Barbiturate Intoxication. F. Herrera Ramos.—p. 376.

Amphetamine Sulfate Therapy of Barbiturate Poisoning.—Herrera Ramos treated successfully 8 out of 9 cases of barbiturate poisoning with amphetamine. The drug was injected intravenously in a solution containing 0.5 mg. of amphetamine sulfate for each gram of the barbituric preparation ingested. This was followed thirty minutes later by an intramuscular injection of the same dose of amphetamine. Intramuscular injections of 1 mg. of amphetamine sulfate for each gram of the ingested barbiturate were repeated every forty-five minutes until the patient recovered from coma. Subcutaneous injection of a solution containing 0.2 mg. of amphetamine sulfate for each gram of the barbiturate ingested was kept up hourly for three hours and every three hours for six hours. Amphetamine sulfate was then given by mouth in doses of 2 mg. every eight hours for twenty-four or forty-eight hours. Determination of the barbiturate level in the blood served as an index to the course of the poisoning and the effect of treatment.

*Cystic Ganglioneuroma of Cerebral Lobe: Histopatologic and Neurosurgic Study. L. Barraquer, E. Tolosa and J. Sard.—p. 225.

Cystic Ganglioneuroma.—Barraquer and his collaborators report a case of cystic ganglioneuroma of the frontal lobe. The proper diagnosis was made from the results of a ventriculography. The operation consisted in frontal osteoplastic craneotomy, elimination of 50 cc. of the cystic fluid through central puncture of the frontal lobe, resection of an area of the cortex 5 cm. in diameter and surgical removal of the tumor. The latter weighed 16 Gm. The histologic diagnosis was ganglioneuroma. The normal cells about the tumor and the walls of the cyst showed that there was neither penetration nor infiltration of tumoral cells to the normal nervous tissues. The operation was successful. The good results have continued five months after postoperative recovery of the patient.

Leukemia and Nervous Complications.—Stodtmeister and Weicker analyzed 300 cases of leukemia from the literature and found that the nervous system is much more frequently involved in a leukemic process than was generally assumed. Hemorrhages, infiltrations and degenerative processes are responsible for the leukemic changes in the nervous system. None of the varieties of leukemia display any predilection for certain areas, tracts or systems in the brain, the spinal cord or the peripheral nervous system. Cerebral hemorrhages can be demonstrated in the majority of the cases in the white substance. Hemorrhages were mainly associated with the periodic appearance of myeloblasts in the peripheral blood in chronic myelogenous leukemia and in the so-called classic myeloblastic leukemia. These processes, however, do not represent a genuine leukemic event but are rather to be considered manifestations of a more or less acute decompensation of the bone marrow function. Disturbances of thrombopoiesis play the main part in the etiology of hemorrhages. Variants of the so-called myeloblastic leukemia, characterized by the presence of tumor-like masses (chloroma), may be responsible for pressure symptoms in the brain or the spinal cord. This type of "myeloblastic syndrome" belongs to the group of true leukemias. Chronic leukemias, particularly those of lymphogenous type, have a tendency to form infiltrations, although hemorrhages may likewise be present. Herpes zoster was observed exclusively in chronic cases, predominantly in those of the lymphogenous type of leukemia. In the absence of signs due to hemorrhage, neurologic symptoms seem to depend on purely degenerative changes. Circulatory disturbances could not be demonstrated. No specific relationship could be established between funicular disease of the spinal cord and the leukemias.

Acta medica Scandinavica, Stockholm

Supplement 144:1-107 (April) 1943

*An Investigation Into a Yeastlike Fungus Isolated from Patients Suffering from or Suspected of Pulmonary Tuberculosis. E. Hollström.—p. 5.

Fungi in Tuberculosis.—The material for Hollström's investigation consisted of five strains of fungus of yeast type, two of which were obtained from the sputum of patients with pulmonary tuberculosis while three strains were isolated from the gastric lavage of patients under observation for suspected tuberculosis. The fungus isolated from these 5 patients was of the yeast-oidium type and was able to produce acid fast rods. When the fungus had been cultivated over twelve months, single cell cultures were obtained by using Chambers' micromanipulator with inverted microscope. Irrespective of their varying capacity to produce acid fast rods, the strains showed varying but the same cultural, tinctorial and biochemical properties. On ordinary slanted agar the fungus grew in colonies which corresponded to the R and S forms of the bacteria, of which the latter was the one most commonly seen. Two types of growth could be distinguished in glycerin bouillon cultures. The staining of the fungus varied to a high degree, so that the acid fastness with the Hallberg stain and the general staining diminished with increasing age of the culture. The acid fast rods may originate from an amorphous mass in the fungus cells, which via non-acid fast granules and filaments differentiate into acid fast elements. Sometimes the outlines of the fungus cells seem to disappear first after this development; sometimes the fungus cells seem to disintegrate before its contents have been differentiated into acid fast elements. Intravenous inoculation into rabbits of agar and glycerin bouillon cultures of the fungus resulted in important variations of temperature, often considerable loss of weight, disturbances of equilibrium, pareses and ocular and other organic changes. The changes in the internal organs were more pronounced shortly after the inoculation than later, with the exception of the eyes. In one rabbit there occurred tuberculoid changes in the lungs, liver and spleen, and from the liver and spleen acid fast rods of Koch's bacillus type were obtained in pure culture. Acid fast rods were further encountered once in renal abscesses and twice in eye abscesses. In nine rabbits fungus cells could be demonstrated in eye abscesses and in three in the central nervous system. No other changes were obtained from inoculation into rabbits and guinea pigs of cultures containing both fungus cells and acid fast rods except such as could be seen after the inoculation with only fungus elements. Animal passage was carried out with material from the rabbit which presented tuberculoid changes in the lung, liver and spleen, and organic changes were produced which in the second passage resembled those of tuberculosis. In the foci there were numerous acid fast rods resembling tubercle bacilli, partly disseminated, partly in small accumulations, some of them phagocytosed and some in large clumps. Inoculation into guinea pigs never produced generalized tuberculous changes. Five of the animals inoculated with material containing acid fast rods were tested with tuberculin with negative results, which was also the case with rabbits inoculated with the fungus strains. From some of the animals cultures were made on Löwenstein's medium, when the acid fast rods grew in a two weeks period into yellowish colonies of twice the size of a pinhead which after recultivation and animal passage presented a changed appearance. The acid fast rods could not be cultivated at living room temperature or at a temperature of 113 F. or on any medium unsuitable for tubercle bacilli.

Book Notices

Treatment by Manipulation in General and Consulting Practice. By A. G. Timbrell Fisher, M.C., M.B., Ch B., Orthopædic Surgeon to the St. John Clinic and Institute of Physical Medicine and to the Arthritic Unit, St. Stephen's Hospital, London. Fourth edition of "Manipulative Surgery." Cloth. Price, $4.75. Pp. 224, with 84 illustrations. New York: Paul B. Hoeber, Inc., 1944.

The art of manipulation in the treatment of orthopedic conditions has been deprecated by many of our best known physicians and surgeons of the past and present generations. The chiropractors and the osteopaths have built for themselves a certain amount of prestige and prominence in the mind of a considerable number of American people by applying the principle of manipulation in spite of the fact that in most instances these practitioners were not qualified to make a correct diagnosis of the condition which they were attempting to treat. The value of careful and skilled manipulation in the treatment of conditions in which there is restricted movement within joints of the extremities resulting from adhesions between muscles, tendons and bursae has been demonstrated by eminent physicians through the centuries. This book is timely and deserves careful consideration on the part of all doctors who are concerned with the treatment of chronic rheumatic diseases or of other conditions which affect the muscles, tendons or joints. The indications for treatment by this method and the technic of manipulation for various conditions has been well described. The book is well worth consideration.

The Amino Acid Composition of Proteins and Foods: Analytical Methods and Results. By Richard J. Bloch, Ph.D., Associate in the Department of Physiology and Biochemistry, New York Medical College, New York, and Diana Bolling, B.S. Cloth. Price, $6.50. Pp. 396, with 5 illustrations. Springfield, Illinois: Charles C Thomas, 1945.

It has been recognized for many years that the nutritive value of protein foods depends on their content of certain indispensable amino acids. Such amino acids cannot be synthesized in the animal body and must therefore be supplied in adequate quantities in the diet. For this reason, as the authors point out in the preface, "a reasonably accurate knowledge of the amino acid composition of a protein permits an approximation of its nutritive value and, more important, allows the choosing of different proteins so that they became mutually supplementary." In this book the authors describe in detail most of the important analytical methods which have been devised for the determination, with some degree of accuracy, of the amounts of the various amino acids commonly found in proteins. In addition they have prepared a large number of tables showing the amino acid composition of a great many nutritionally valuable food proteins of plant and animal origin. The result is a book which will be found invaluable not only by the biochemist interested in the quantitative determination of some particular amino acid but also by the clinician and the dietitian interested in formulating diets which include all of the essential amino acids in adequate amounts. It will also be found extremely useful in helping to select dietary proteins which are rich in some particular amino acid to be included in the diet for therapeutic purposes.

An Invitation to Portuguese. By Margarita Madrigal and Henriqueta Chamberlain. Cloth. Price, $1.75. Pp. 208, with illustrations. New York: Simon and Schuster, 1944.

As contacts with the medical profession of Brazil become more frequent, more physicians will be interested in developing at least a sufficient knowledge of Portuguese to enable them to get about successfully when visiting that country. This manual is designed particularly for those who want to learn such a minimum amount of Portuguese rapidly.

My Second Life. By Thomas Hall Shastid, A.M., M.D., LL.D. Cloth. Price, $10; Ragston permanent paper edition, $12. Pp. 1,174, with illustrations. Ann Arbor, Michigan: George Wahr, 1944.

In 4 pounds 12 ounces of war-scarce materials comprising 1,174 pages, this volume stands 3⅝ inches thick. It is the author's second autobiography. It is an almost incredible collection of reminiscences without apparent organization.

American Medical Practice in the Perspectives of a Century. By Bernhard J. Stern, Ph.D., Visiting Professor of Sociology, Yale University, New Haven. Cloth. Price, $1.50. Pp. 156. New York: Commonwealth Fund; London: Oxford University Press, 1945.

This is one of a series of monographs to be offered by the Committee on Medicine and the Changing Order of the New York Academy of Medicine. It contains much interesting information but at the same time offers statements which may be attacked vehemently by those who have been closer than the author to the prevention, diagnosis and treatment of illness. While the book seems to be a plea for "socialized medicine," it actually makes no such plea directly.

Here is a strange comparison from the chapter on "The Expanding Horizons of Medicine":

> A comparison of the records of 2 patients with heart disease, 1 admitted to the hospital about twenty-five years ago and another admitted to the same hospital in 1938, yields interesting results. The first patient was cared for by a visiting physician, an intern and one specialist, the pathologist, bacteriologist, and the completed record covered two and one-half pages. The second patient was observed and described by three visiting physicians, two residents, three interns, ten specialists and fourteen technicians, a total of thirty-two individuals, and though the record of the case was still incomplete, it already covered twenty-nine pages.

This example, which, according to the author, was taken from G. Canby Robinson's The Patient as a Person, is not typical of the changes in the practice of medicine. Any one familiar with hospitals and modern treatment of disease is aware that the average patient is not seen by a variety of experts. A patient will be visited by an intern and a resident physician, as this is part of their duties. The attending physician will have full charge of the average case and he will call in a consultant only when necessary. If laboratory work is needed it will be provided. Yet the author claims, on page 53, "Considered from the viewpoint of the patient, specialization has complicated medical care in manifold ways and increased costs tremendously."

On page 54 the author claims that "there is little doubt but that the specialist tends to confine his observation of the causes of illness to the narrow field of vision with which he is most familiar. His special training and experience bring certain symptoms into focus, while his lack of experience in other fields dims his appreciation of the meaning of equally important symptoms. He fails as a rule to consider the patient as a whole, either physiologically or psychologically. Moreover, as patients, for the most part, come to the specialist only after their diseases are well advanced, the specialist's approach tends to be almost exclusively curative and only incidentally preventive." Then, he states, "it is one of the disparities of modern medicine that, while developments in the field of the deficiency diseases, endocrinology, psychiatry and psychosomatic medicine have led to the consideration of the patient in the context of his life history, the trend of diagnostic specialties is to ignore as irrelevant anything but the particular matter under scrutiny."

Apparently Stern believes that physicians do not yet receive adequate education, as he writes "The education of the physician not merely as a technician, but as a cultured person equipped with insights into human relationships and sensitized by an appreciation of the social sciences and the liberal arts, will do much to humanize the patient-doctor relationship, whatever other factors may tend to formalize such a relationship."

Somehow the author has the idea that practice in an office rather than in one's home is not conducive to establishing good patient-doctor relations: "The doctor formerly met his patients in a room set aside in his home, and the neighbors, when ill, came to see him and were received somewhat in the manner of guests. When his office is removed from the neighborhood to the center of town the contact is more impersonal and it is further formalized when receptionists and nurses take records. The further shift of diagnosis and treatment from the home to the hospital also reduces the physician's opportunity to acquire first-hand knowledge of the family setting and economic background of his patients."

Increasing interest is being shown in the family background of his patients by most physicians, general practitioners or specialists because they realize that there may be hidden in this background factors which may influence the mental and physical condition of the patient. Thus one cannot agree entirely with the statement "It is because pediatricians have intimate contacts with families in their homes that they have more affectionate relations with their patients than do other specialists whose

home visits are relatively infrequent." Apparently one of the most important human driving forces has been overlooked, namely the love that parents have for their children and the personal sacrifices that they will make to insure the welfare of a child. While they may not be particularly concerned about their own health or be especially interested in having their personal problems adjusted, they usually will abide unquestionably by suggestions from a physician when it has to do with their children.

There are other passages needing comment but there is not sufficient space. Unfortunately so much time was apparently devoted obtaining statistics concerning medical practice that the interpretations seem to be unsupported by known facts. Figures alone will not tell the whole story. Statistics must be properly evaluated; adequate evaluation can be made only by one familiar with the practical aspects of the problem.

A Method of Anatomy: Descriptive and Deductive. By J. C. Boileau Grant, M.C., M.B., Ch.B., Professor of Anatomy in the University of Toronto. Third edition. Fabrikoid. Price, $6. Pp. 822, with 729 illustrations. Baltimore: Williams and Wilkins Company, 1944.

In this edition fifty-five illustrations have been added to the original list; about seventy have been redrawn and relabeled. The initial section deals in general fashion with the several bodily systems. The osseous structure is considered microscopically; vascular foramens, elevations, facets, foveas and other gross features are discussed. Muscles are described on the basis of fascicular architecture; the physiologic mechanism of contractions is described in simple terms. The vascular system is considered from the standpoints of blood volume, character of arteriovenous anastomoses and nature of sinusoids, arteries and cavernous tissues. Many helpful facts are recorded regarding vascular patterns in such special areas as the nail bed, lip, cerebrum, spleen and erectile bodies; topographically different parts are thus brought together on the basis of peculiarity in blood supply. By this means the student is introduced to a rationalizing scheme of study. The nervous, digestive, respiratory, urinary and reproductive systems are similarly treated in this preliminary section. The regional accounts follow, a section being devoted to each of the major subdivisions of the body. A closing section covers the autonomic nervous system, body types and the separate elements of the skeleton. In all of these sections anatomic detail is handled ingeniously through the employment of simple mechanical principles; familiar physical notions are abundantly cited in order to render structural facts mentally manageable. For example, the inguinal canal is likened to a channel whose roof consists of three arcades contributed by a trilaminar wall; the liver is described as resembling an oblong block; the space of the femoral triangle, with its continuation as adductor canal, is likened to a funnel with a long spout. The section on thoracic anatomy, in addition to dealing with the regular segregated items, discusses such varied general topics as posture, alteration in form of the bronchial tree, development of the heart and great arteries. The section on the anatomy of the head and neck is, like the preceding sections, replete with diagrammatic figures.

The Method of Anatomy resembles a manual more closely than it does any other type of treatise, but it differs from the standard manual in presenting concepts superabundantly. It is not a textbook of the regular systematic order, since it is arranged chiefly on a regional basis. It is not a substitute for an atlas, since the drawings are diagrammatic. The book is unique in its attempt to teach anatomy in such a way that underlying principles, rather than mere facts, are made its chief content. Only a gifted teacher could formulate as many valuable notions as Professor Grant has included in his volume. His experience has allowed him to furnish some of the cleverest bits of description yet encountered in anatomic writings.

While Professor Grant's provocative volume could not replace the regular books in a student's anatomic library, it could most profitably be added to such a library. For the advanced student its content is inspiring; the surgical anatomist will find it useful as a source book for lecture material; and the novitiate in gross anatomy who places partial dependence on its ingenious text and pictures will be carried glowingly through those beginning years which, customarily, are far too didactic.

Health Practice Indices 1943: A Collection of Charts Showing the Range of Accomplishments in Various Fields of Community Health Service. Compiled from the Evaluation Schedules Submitted for the Year 1943. Prepared by the Subcommittee on Manual of Practice and Appraisal of Local Health Work for the Committee on Administrative Practice of the American Public Health Association. Paper. Pp. 116, with illustrations. New York, [n. d.].

This is a useful publication for the health officer who is serious about measuring the work of his health department or of the total health effort in his community against standardized practices in the field. The American Public Health Association has based most of its appraisal work comparisons with what is actually being done in various phases of public health work. Thus it becomes possible to compare the work in a given city not with a theoretical ideal but with the best work, or the worst, or the mediocre actually being accomplished. In the course of some twenty years since the first efforts at objective appraisal were made, a large volume of information has been built. Against this the health officer in any community can measure the health work done in that jurisdiction. So also can any interested group of citizens, professional or lay.

This collection of charts deals with health department personnel, general hospital beds, communicable disease control, tuberculosis, syphilis, gonorrhea, maternal health, infant health, preschool health, school health, accidental death, sanitation, public health expenditures and a list of health departments reporting and a table of summaries which gives the range of performances, the medians and other pertinent factors involved in interpreting the several tables. A typical section is that on communicable diseases, which contains nine charts preceded by a general summary in which each chart is briefly explained in a paragraph. The first chart deals with cases of smallpox reported over a five year period, the second chart with whooping cough, the third with diphtheria cases per hundred thousand of population in a five year period. The next chart deals with diphtheria deaths and the next two deal with typhoid cases and deaths respectively. The seventh chart gives a record of the percentage of cases of typhoid and paratyphoid investigated in the five year period, and the eighth the percentage of sources found. Chart 9 records cases of malaria reported per hundred thousand of population in a five year period.

Only a few charts indicate universally satisfactory accomplishment. Under sanitation, for example, the chart showing the rural school population percentage served with approved water supplies shows less than half of the upper quartile at 100, the rest of the reports in this quartile ranging to just above 90. As these graphs are constructed, satisfactory accomplishment would indicate the extension of the horizontal bars from the left as close to the right as possible. In other words, a practically solid chart of bars approaching 100 per cent would indicate a high level of accomplishment. Actually, most of the charts have large white spaces indicating by that just so much failure of public health practice to live up to the best standards of actual performance reported entirely aside from any comparison which might be made between the best standards attained and theoretically acceptable standards of performance. These charts indicate that there is so much to be done to bring accepted standard public health practices to an acceptable state of performance that there is little or no justification for attempting to load onto health departments the burden of administering medical care, as contemplated by the recent declaration by the American Public Health Association.

Lectures on Diseases of Children. By Sir Robert Hutchison, Bart., M.D., LL.D., F.R.C.P., Consulting Physician to the London Hospital and to the Hospital for Sick Children, Great Ormond Street, and Alan Moncrieff, M.D., F.R.C.P., Physician to the Children's Department, Middlesex Hospital, London. Ninth edition. Cloth. Price, $6.75. Pp. 478, with 108 illustrations. Baltimore: William Wood & Company, 1944.

The fact that this little volume has reached the ninth edition is convincing evidence of its popularity. The authors of these Lectures on Diseases of Children make no effort to cover the field of pediatrics, nor do they undertake a comprehensive coverage of the subjects which they discuss. The material is distinctly clinical and thoroughly practical. The lectures offer easy and instructive reading for the medical student, the general practitioner and the pediatrician.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

IMMUNIZATION WITH MULTIPLE ANTIGENS

To the Editor:—The multiplicity of immunizations currently used by the U. S. Army has led to the question of the possibility of using mixtures of vaccines, particularly those of typhoid-paratyphoid, cholera and typhus. We have used such mixtures on several thousand men with no untoward results. The benefits included an increase in the accuracy of dosage and in economy of time, equipment and personnel. There were no known disadvantages. The consensus among both medical officers and those receiving the immunizations was that there were many advantages, not the least of which (to the patient) were the fewer skin punctures required, with corresponding decrease in the possibility of injection: The mixture used was:

Vaccine	Manufacturer	Volume
Cholera, (8 billion killed vibrios per cc.)	Eli Lilly & Co.....	1 cc.
Typhus (from yolk sacs of chick embryos)	E. R. Squibb & Sons.....	1 cc.
Triple typhoid	Army Medical School.....	0.5 cc.

Is there any evidence that such mixtures are not as effective if given in one mixed injection as if they are injected simultaneously at different sites? Are there any other possible disadvantages?

Major, M. C., A. U. S.

[This inquiry was referred to two authorities, whose respective replies follow.—EDITOR.]

ANSWER.—Combinations of several antigens have long been employed in immunization of man, some of them in the first world war. There is no important evidence to indicate that the vaccines are less effective given in one mixed injection than when the components are injected simultaneously at different sites. In the United States at present a combination of triple typhoid vaccine with diphtheria toxoid and tetanus toxoid has been proposed as well as a combination of pertussis vaccine with the two toxoids. The full activity of the several antigens is probably preserved in these combinations. The combination mentioned (cholera, typhus and triple typhoid) does not appear to have been the subject of published reports but might be expected to yield whatever results could be reasonably anticipated from the administration of the several vaccines separately.

ANSWER.—The use of multiple antigens has become a well established practice. Blood titrations on persons receiving combined diphtheria and tetanus toxoids show antitoxin levels of the same value as when these antigens are used separately. The addition of pertussis vaccine to diphtheria toxoid does not cause greater reaction or less evidence of immunity than when used separately. The Canadian army uses triple typhoid vaccine combined with tetanus toxoid. The resulting typhoid antibody level is at least equal to that of vaccine alone, whereas the tetanus antitoxin level is definitely higher. The French in Africa have combined smallpox and yellow fever vaccine into a single inoculation by scarification. They report no lessening of the immunity level for each. The reaction to be expected from combined antigens is approximately the sum of the individual reactions, which in the combination mentioned in this query would be that of triple typhoid vaccine since the other two rarely produce constitutional reactions. There are three problems to be solved in selecting the antigens to be combined: 1. Are the individual antigens compatible? Yellow fever vaccine, being a live virus and delicate, could not be mixed with any of the killed antigens. 2. What combination of antigens is needed for the persons to be immunized? A combination such as typhus vaccine and diphtheria toxoid would never be required, whereas triple typhoid vaccine and tetanus toxoid is a good one for military purposes and would not be objectionable in civilian life. 3. Occupation, age, social status and geographic location are factors which will influence the combinations that will be useful. Likewise the rate of immunity development, the age when immunity is particularly needed and the duration of immunity are factors of importance.

IONIZATION THERAPY IN OPHTHALMOLOGY

To the Editor:—Will you please let me know the status of ionization therapy in diseases of the eye?

M.D., Michigan.

ANSWER.—The simplest answer to this question is that ionization in disease of the eye is still in the experimental stage. There have been few reports of the clinical use of drugs by ionization in the literature in recent years. Von Sallman recently reported the iontophoretic introduction of atropine and scopolamine into the rabbit's eye. He used a Birkhauser electrode, which fits on the cornea like a contact lens. Using a 45 volt dry cell battery delivering 2 milliamperes for two minutes, he found that six to nine times as much atropine was found in the aqueous with this procedure as with an ordinary corneal bath used for the same length of time. Also he determined that with a transscleral electrode the delivery of atropine into the aqueous was not nearly as good. Since the outbreak of war a clinical report by Fleming has described the electrical device and gives a few case reports. He recommends iontophoresis in lid conditions, especially to break up adhesions in the iris. An excellent review of the entire subject appeared in *Ophthalmologica* in 1939. The author, Karbowski, lists the anions and cations which may be used and indicates in what disease conditions of the eyes each is of value. In the American literature Erlanger, who did most of his work in Germany, attempted to stimulate interest. The obvious conclusion would seem to be that electrical therapy is seldom needed in the treatment of the majority of eye diseases.

OBSCURE FEBRILE ILLNESS

To the Editor:—A man aged 34, weighing 138 pounds (63 Kg.), 5 feet 8 inches (173 cm.) tall, has been in the Army since July 1942 on full field duty. The early history is essentially normal; he had the usual childhood diseases. In 1942 he had an attack of streptococcic sore throat from which an uneventful recovery was made. He was sent to the China-Burma-India theater of operations doing full field duty from August 1943 until October 1944, spending most of this time in China and Burma. In 1943 he was hospitalized for bacillary dysentery and later sent back to duty as cured. In 1944 a laboratory diagnosis of relapsing fever was made and the usual arsenical treatment was given. About this time a tumor, diagnosed as a synovioma of the usual grade of malignancy, was removed from his right foot and he was returned to duty. A few months later he was sent to a hospital, where a diagnosis of malaria (Plasmodium vivax) was made and a course of treatment given. Symptoms of headache, joint aches and pains, 45 pounds (20 Kg.) loss of weight, weakness, nervousness, anxiety, anorexia, insomnia, generalized abdominal soreness and vague chest pains persisted and he was sent to another hospital with a diagnosis of possible undulant fever because of a persistent low grade undulating type of fever (99 to 101 F.). Agglutination tests at this time showed a positive reaction for paratyphoid B. Various sulfonamide compounds were administered, but symptoms persisted. Examination of the stools gave a negative reaction for typhoid and amebic dysentery. He was finally sent to a general hospital with a diagnosis of paratyphoid B and traumatic arthritis of the right foot due to repeated trauma. He was later sent to a general hospital in the United States with a diagnosis of febricula and a mild anxiety state. Fever and other symptoms have persisted for almost seven months. Agglutination and skin tests have given normal reactions. Blood cholesterol and sedimentation rates have been up and down and are now within normal limits. The heart, lungs, kidneys, prostate, eyes, ears, nose and throat have been cleared and no other foci of infection have been found; however, the patient's general condition remains unchanged. Would one be justified in considering the possibility of there still being present an undiagnosed undulant fever? What impressions, suggestions and comments can be made on the basis of this history?

Captain, M. C., A. U. S.

ANSWER.—None of the various diagnoses with the possible exception of undulant fever could account for the persisting symptoms. The tentative diagnosis of chronic brucellosis is still justified despite the negative intradermal tests and the absence of specific serum agglutinins. The history suggests a recrudescence of brucellosis which was probably acquired many years ago, possibly in childhood, and which may have been either frank and undiagnosed or wholly subclinical at that time. A more detailed history of infantile and childhood behavior and complaints, places of residence, sources of dairy products, with similar information about parents and siblings might provide supportive evidence. The unlikely, but possible, event of infection with Leptospira canicola could probably be excluded by an agglutination test with the patient's serum against this strain of Leptospira. Opsonocytophagic tests, and repetition of agglutination tests against Brucella, ultimately followed by repetition of intradermal tests with brucellergen, are indicated. If all tests remain persistently negative it would be justifiable to employ the therapeutic test with Brucella vaccine, administering small amounts of highly diluted vaccine over a period of several months.

TOXICITY OF HIGH OCTANE GASOLINE

To the Editor:—I should like information on the toxicity of inhaling fumes from high octane gasoline as used in airplanes. Is there danger of lead poisoning? Are there any toxic effects of direct contact with this type of gasoline?

Captain, M. C., A. U. S.

ANSWER.—The dangers of respiratory exposure to the hydrocarbons and their derivatives found in high octane aviation gasoline depend on the concentration of these vapors and the duration of the exposure. Generally speaking, prolonged inhalation of the vapors of ordinary gasoline is harmless, provided the concentration in air does not exceed 1,000 parts per million. Perhaps some decrease in the accuracy of cerebration and of fine muscular coordination may result from such exposure, but these effects are generally slight and disappear promptly after discontinuance of the exposure. High octane gasolines usually contain hydrocarbons not found in ordinary gasoline, and some of these are much more toxic than those that characterize ordinary gasoline. Accordingly the concentration of vapors of high octane gasoline should not exceed 500 parts per million for comparatively short periods of exposure. It is probable that this concentration is too high for regularly repeated prolonged exposures (hours), and it is certain that concentrations of this order of magnitude should not be permitted to occur for more than fleeting periods within aircraft because of the effect on the efficiency of operating crews The acute effects of exposure to high concentrations of all gasoline vapors are much the same. Intoxications and varying degrees of narcosis occur promptly. Recovery following removal from exposure or following resuscitation is usually complete but not always prompt. There is little risk of serious exposure except under conditions of excessive spillage or evaporation within enclosed or poorly ventilated spaces.

Significant lead absorption from inhalation of the vapors of leaded gasoline occurs only from prolonged and frequently repeated exposure under conditions of excessive spillage and evaporation of gasoline within poorly ventilated spaces. The avoidance of spillage, leakage and especially a fine spray of gasoline, and the control of the hazards of fire and explosion in a manner consistent with the accepted practices employed in the commercial distribution and handling of gasoline will suffice to prevent any significant hazard of lead absorption.

There is no danger of lead poisoning as the result of cutaneous contact with this type of gasoline. The local effects of skin contact with this or any other gasoline, under suitable circumstances, are burning and blistering of the skin, defatting of the skin followed by drying and fissuring and perhaps secondary infection or parasitic infestation, and occasionally, following frequently recurring contact, a dermatitis of varying severity. These effects are produced by the hydrocarbons.

VITAMIN P

To the Editor:—A woman aged 40 says that she needs vitamin P (hesperidin). What are the symptoms of lack of this particular vitamin? Where may vitamin P be obtained?

Thomas van Urk, M.D., Kalamazoo, Mich.

ANSWER.—The occurrence of a disease entity resulting from lack of vitamin P (hesperidin) is undecided. There is clinical evidence that administration of vitamin P preparations favorably affects the lowered capillary resistance or spontaneous petechial hemorrhage associated with multiple vitamin deficiencies and found in certain diseases. Large doses of vitamin C promptly alleviate the gross hemorrhage manifestations of scurvy, but neither vitamin C nor vitamins A, B_1 or D appear to raise the lowered capillary resistance which can be corrected by vitamin P. On the other hand this vitamin cannot substitute for vitamin C. A vitamin P deficiency showing spontaneous petechial hemorrhage has been postulated as differing from the spontaneous gross hemorrhage of scurvy.

There have been a number of reports on the use of vitamin P in hemorrhagic purpuras associated with blood dyscrasias or toxic agents in which symptomatic improvement has been obtained. These relate to the purpura found in allergy and in infection and that resulting from antisyphilitic therapy as well as in situations characterized by vascular rupture in mucous membranes of the mouth, the gastrointestinal tract and the renal tract. Improvement in psoriasis has been reported from the use of vitamin P.

This vitamin is found in significant concentration in orange or, better, in lemon peel. The vitamin P content is approximately 1.75 mg. per gram of whole lemon. It is readily extracted by boiling the sliced whole fruit in water for ten minutes. The solution should then be strained and sweetened to taste. An empirical dosage of 20 mg. of vitamin P twice daily has been suggested, since the therapeutic requirement is not known. The purified vitamin is not available commercially at the present time.

ICHTHYOSIS

To the Editor:—A boy aged 3 years has ichthyosis, chiefly on the arms and legs, with a little on the back along the spinal column. I have been giving him 100,000 units of vitamin A daily, and improvement has been great; aside from the liberal use of lanolin on the affected areas, no other therapy has been given. 1. Is this amount of vitamin A likely to produce any unfavorable symptoms if continued over an indefinite period? 2. I have been advised to give the child ½ grain (32 mg.) of thyroid daily; is this dose harmful to a child 3 years of age? The ichthyosis has improved considerably without this therapy already. 3. Is the use of soap and water to be avoided? I have encountered contradictory advice in this regard.

M.D., Texas.

ANSWER.—1. Mild ichthyosis is often alleviated considerably by the administration of vitamin A in fairly large doses. Many patients do well in the summer anyway, so that it seems advisable to use the vitamin A only in the cold weather. No unfavorable symptoms have been reported from the administration of vitamin A, but intermittent use is advised on general principles.

2. In a case like that mentioned thyroid would not seem necessary, although it is occasionally of help.

3. In general, the less soap and water the better in mild ichthyosis; many patients need some oil or grease, especially in cold weather, to make them more comfortable.

MYELOCYTES AND NORMOBLASTS IN SPINAL FLUID

To the Editor:—What condition will produce myelocytes and normoblasts in the spinal fluid, the peripheral blood being negative for these forms? This is a case of apparent infectious meningitis, but no organisms have been isolated. The humerus shows several punched out areas. There are no other abnormalities.

M.D., South Carolina.

ANSWER.—There is apparently no recognized condition in which myelocytes and normoblasts are found in the spinal fluid. It is theoretically possible that, with a destructive lesion of the skull or vertebrae, bone marrow cells might migrate directly into the spinal fluid. Also a focus of extramedullary hemopoiesis could be associated with this phenomenon.

Myelocytes have been found in the spinal fluid of patients with chronic myelocytic leukemia. However, in this condition they are present also in the peripheral blood.

TREATMENT OF TYPHOID CARRIERS

To the Editor:—May I amplify the reply to the query regarding treatment of typhoid carriers as published in The Journal, Feb. 17, 1945, page 428 from two sources of information? First, the *Annals of Surgery* (105:791 [May] 1937) contains an article entitled Surgical Treatment of Chronic Biliary Typhoid Carriers, by Dr. F. A. Coller, University Hospital, Ann Arbor, Mich., and Dr. F. C. Forsbeck, Michigan State Department of Health. They report the removal of the gallbladder from 18 typhoid carriers. Sixteen were cured, as evidenced when specimens of feces at monthly intervals for twelve months showed no typhoid organisms. Second, a report to the Detroit Department of Health was made in 1936, which reads in part as follows: "The typhoid carrier is a person who harbors, for an indefinite period, typhoid organisms. When the opportunity arises, typhoid fever may develop among contact persons. Sometimes the carrier has suffered from the disease, and at other times he does not recall having had typhoid fever. The site of infection is usually the gallbladder or the urinary bladder. It is sometimes found in discharging sinuses, and at other times the primary focus is in the intestinal tract—perhaps the appendix. The typhoid organism is often found in the appendix when it is present in the gallbladder. In the literature there are many series of typhoid carriers reported in which the gallbladder has been removed with the result that 70 per cent or more recovered from the typhoid carrier state. Sinuses which contain typhoid organisms, when treated surgically and closed, are cured at once. Urinary typhoid carriers are often treated successfully with urinary antiseptics. Gallbladder surgery on children and those over 50 years of age is often not desirable. Provision for the education of these children and provision of means for earning a livelihood for older carriers is often a difficult problem. Several states have supplied funds which will provide for the medical care and for the support of carriers who are deprived of their livelihood because of their carrier state." An interesting instance of a child typhoid carrier being cured by cholecystectomy is hereby reported: The child was born in 1929 and had typhoid in 1935. Numerous cultures from her feces up to 1940 contained typhoid organisms. Apparently her uncle developed typhoid from her and died. A neighbor's child, a playmate, developed typhoid. The child carrier was deprived of schooling. She was called to the attention of Dr. Grover C. Penberthy, who placed her in the Children's Hospital and removed her gallbladder. After three weeks repeated specimens of feces were examined and no typhoid organisms were found. She returned to school within a year. The observation has been made that sometimes the surgeon is interested only in the removal of the gallbladder and cuts the cystic duct some distance from the common duct, thus making a pocket of the cystic duct in which typhoid organisms can multiply. Such an operation might not cure the typhoid carrier. It therefore seems important when removing the gallbladder from typhoid carriers to cut the cystic duct near the common duct, so that a pocket at the side of the common duct will not be formed.

THIOURACIL IN THE TREATMENT OF THYROTOXICOSIS

ROBERT H. WILLIAMS, M.D.
AND
HOWARD M. CLUTE, M.D.
BOSTON

There have been several reports [1] of the use of thiouracil in the treatment of thyrotoxicosis since Astwood's [2] important discovery of the value of this drug, but most of these have dealt with only small series of cases. Now, however, we report on the use of this drug in the treatment of 152 patients with hyperthyroidism. The age of the patients varied from 5 to 72 years, and the thyrotoxicosis had existed for from three weeks to twenty-two years. One or more subtotal thyroidectomies had been performed in 17, and 29 had taken iodide until less than a month before thiouracil therapy was begun. In 7 instances iodide therapy had been discontinued because of the development of an associated rash. While most of the patients had diffusely hypertrophied thyroid glands, many had nodular goiters. In 23 cases there were clearcut symptoms of myocardial insufficiency with cardiac dilatation and hypertrophy, and in 5 there was pronounced congestive heart failure. Thirteen had varying degrees of thyrotropic ophthalmopathy or malignant exophthalmos, and 2 had thyrotoxic myopathy. Two patients were treated during the last month of pregnancy and 1 for the first eight months of pregnancy.

Before beginning thiouracil [3] treatment the patient's general condition was evaluated, particular attention being paid to the degree of thyrotoxicity, the condition of the orbital structures and the characteristics of the thyroid gland. Determinations were made of the pulse rate, weight, basal metabolic rate and sometimes the protein bound iodine of the plasma. Most of the first 20 patients were hospitalized and were studied from various points of view. However, few of the patients subsequently treated were hospitalized for more than one day, if at all.

TREATMENT

It is important to choose the optimum dosage of thiouracil, since excessive amounts will increase the incidence of the toxic effects from the drug and may increase the size of the goiter as well as accentuate the manifestations of malignant exophthalmos. On the other hand, it is desirable to use a sufficient quantity to cause a remission within a few weeks. Having used many different dosages, we prefer in most cases to administer 0.5 or 0.6 Gm. daily for the first two weeks, then 0.3 or 0.4 Gm. daily until the basal metabolic rate has become normal, and then 0.1 Gm. twice daily. After two or three months the dosage can be reduced to 0.1 Gm. daily. Since thiouracil is rapidly absorbed from the gastrointestinal tract, rapidly destroyed in the body and rapidly excreted,[4] it would seem desirable to administer the drug at frequent intervals throughout the day. Although we have tried this it has not been possible clinically to demonstrate that it is ever necessary to give more than three doses daily.

Desiccated thyroid has been used to decrease the size of the thyroid gland in 10 patients and to antagonize the effects of thyrotropic ophthalmopathy in 6. It was administered in daily dosages of 32 to 96 mg. for several weeks.

Roentgenotherapy was applied to the thyroid gland in 6 cases. In each case there was diffuse hyperplasia of the thyroid, and a remission of the thyrotoxicity had been induced with thiouracil treatment. To each lobe of the thyroid was applied 200 roentgens at weekly intervals for four to eight weeks in order to decrease the size of the thyroid gland. Thiouracil treatment was continued as usual in all cases.

Subtotal thyroidectomy has been performed in 59 cases. The basis for choosing this treatment rather than prolonged treatment with thiouracil was (*a*) the existence of a very large goiter, (*b*) the development of urticaria or agranulocytosis during therapy, (*c*) factors interfering with careful observations of the patient —business obligations, ignorance, uncooperative attitude, temperamental reactions, psychoneurosis or distant residence—and (*d*) request by the patient for thyroidectomy.

Read before the Section on Experimental Medicine and Therapeutics at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1945.

Thiamine was commonly prescribed, as were sedatives. Recently, brewers' yeast has been administered routinely with the hope of protecting against agranulocytosis. Most of the patients were permitted to continue with their regular work; in fact, many never missed a single day of work. They were examined every one

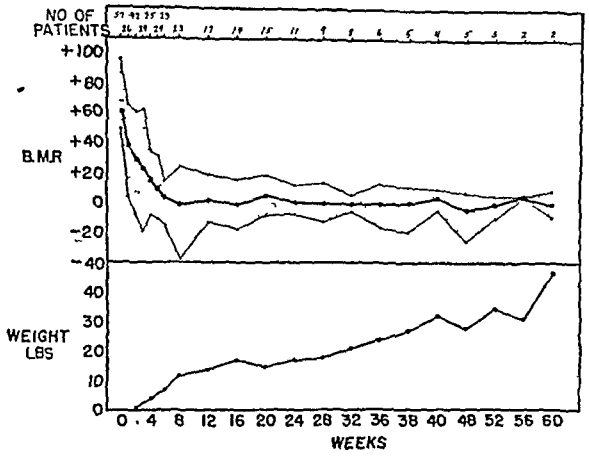

Fig 1.—The average response to thiouracil treatment of the basal metabolic rate and weight of 57 patients with moderately severe or severe thyrotoxicosis. The shaded area is formed by plotting the highest and lowest values for basal metabolic rate at the time intervals indicated. Note the progressive fall to normal in the basal metabolism, requiring six weeks, and its maintenance at this level. Although there was no average gain in weight in the first two weeks, there was a progressive and well defined gain thereafter.

to two weeks for the first six weeks, at monthly intervals for about the next four months and at six to eight week periods thereafter. All were instructed to consult one of us in the case of fever, symptoms of "the grip," sore throat, or any infection—disturbances suggesting agranulocytosis.

RESULTS OF TREATMENT

Thiouracil Without Thyroidectomy.—Improvement in the thyrotoxicity began within a very few days after commencing thiouracil, and within three to seven weeks there was a disappearance of nervousness, tremulousness, tachycardia, hyperpyrexia, diarrhea and hyperhidrosis. Within the first two weeks there was but little gain in weight, but it occurred rapidly thereafter. Almost all of the patients with malignant exophthalmos experienced an exacerbation in the orbital changes, but patients with nonmalignant exophthalmos exhibited a decided

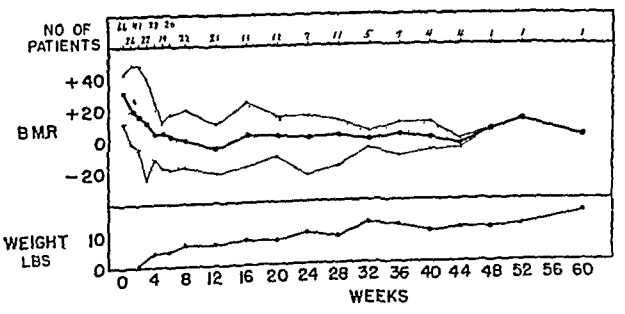

Fig 2.—The average response to thiouracil treatment of the basal metabolic rate and weight of 66 patients with mild thyrotoxicosis. Except for less magnitude, the changes are the same as in figure 1.

improvement or disappearance of this disturbance. The thyroid gland in most subjects showed little change; in some it became smaller and in a few it became larger and firmer. In most patients the bruit disappeared. The basal metabolic rate became normal within two to seven weeks, the average time being six weeks in the severer cases (fig. 1) and four weeks in the less toxic ones (fig. 2). The protein bound iodine of the plasma became normal[4] sooner than the basal metabolic rate (fig. 3).

With the continuation of thiouracil treatment the clinical remission has been maintained in all cases. Ten patients have been treated continuously for more than a year, 36 for more than eight months and 52 for more than four months. Since the first month or two all have remained essentially free of thyrotoxic symptoms and signs and have maintained a normal basal metabolic rate. In 4 cases with thiouracil continued for approximately a year and in 1 treated for six months the drug was omitted to determine its further need. One subject has maintained a normal status for six months, and 4 have remained normal for two to three months (fig. 4). However, 1 had a relapse after two months. Two other patients have discontinued therapy of their own accord on three separate occasions after they had been in a remission for about three months. Each time a recurrence of thyrotoxicosis appeared in about a month, and it required another month to gain a remission. However, patients treated for only a few weeks experienced a recurrence within two or three weeks.

With the aid of roentgenotherapy in 6 patients or treatment with desiccated thyroid in 10, in almost all of the 152 persons treated with thiouracil for more than four months there has been a reduction in the size of the thyroid. In 23 patients the thyroid gland was two to four times normal in size before treatment, but after prolonged treatment it was only one to one and a half times normal.

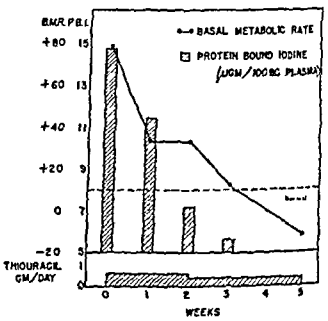

Fig 3.—Response to thiouracil treatment of the basal metabolic rate and protein bound iodine of the plasma in a patient with severe thyrotoxicosis. In this case, as in others, the iodine was found to return to a normal range (4 to 8 micrograms per hundred cubic centimeters) sooner than the basal metabolism.

Although most patients with malignant exophthalmos experienced an exacerbation soon after taking thiouracil, with the institution of desiccated thyroid each showed improvement, which was pronounced in some cases.

The 29 patients who had had iodide until less than four weeks before beginning treatment with thiouracil improved more slowly than described in the previous paragraphs (compare figure 5 with figures 1 and 2). During the first two or three weeks of thiouracil therapy there was commonly no improvement in patients who had had iodide and, in fact, not infrequently there was an increase in the thyrotoxicity. It has been found that an exacerbation did not occur if the iodide therapy was continued in very small and gradually reduced doses during the first two weeks of thiouracil treatment. Nevertheless the patients previously treated with iodide required an average of about four weeks longer to obtain a remission of their disease than did patients treated with only thiouracil. Occasionally the response was as good as in the cases in which thiouracil was administered and no iodide.

In 5 cases, owing to the development of toxic reactions from thiouracil, iodide therapy was instituted. It seemed to have but little effect in 2 cases, even after several weeks of treatment, but was satisfactory in the other 3.

Thiouracil with Thyroidectomy.—Of the 59 thyroidectomized patients 29 had never had any iodide, 14 had had iodide for varying intervals before thiouracil was used, 12 received iodide and thiouracil simultaneously and 4 had had thiouracil replaced with iodide. The last group consisted of patients who developed toxic reactions to thiouracil and were then treated with iodide and thyroidectomy. Their course was essentially as though no thiouracil had been given and needs no further consideration. The preoperative response of the patients who received no iodide until after thiouracil therapy was started was similar to the response obtained in subjects treated with thiouracil alone.

Thyrotoxic manifestations during thyroidectomy were distinctly less severe in the cases treated with thiouracil than in a comparable group treated with iodide. A good state of anesthesia was readily secured with cyclopropane. During the operation the maximal pulse rate of the thiouracil treated patients varied from 79 to 155 and averaged 113 (fig. 6). The maximal systolic blood pressure varied from 65 to 165, while the maximal diastolic pressure varied from 65 to 130, averaging 93. The thyroid gland tended to be more friable and to ooze more than in patients prepared with iodide, and occasionally adhesions extended from the thyroid capsule to surrounding structures.

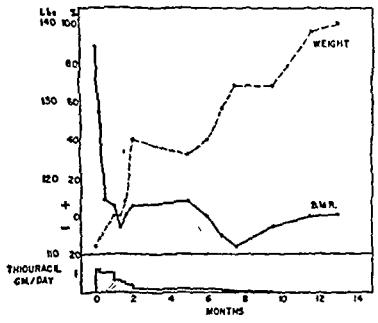

Fig. 4.—Response of the basal metabolic rate and weight of a severely thyrotoxic patient treated with thiouracil continuously for nine and one-half months. A remission has been maintained for three and one-half months after discontinuation of therapy. The plasma protein bound iodine preceding treatment was 12 micrograms per hundred cubic centimeters.

The postoperative course was definitely smoother than in patients treated with iodide. The patients were calmer and had less cardiorespiratory distress. The maximal pulse rate postoperatively varied from 88 to 140, averaging 109. Excepting in 2 cases the pulse never exceeded 125. The average maximum temperature was 100.6 F. and the temperature never exceeded 102 except in 1 case. One patient who had had a smooth course until three hours after operation suddenly experienced respiratory distress and died within five minutes, apparently from embolism.

Preceding thyroidectomy the patients were treated with thiouracil for from eight to two hundred and forty days, averaging forty-two days. It soon became apparent that patients who were treated until the basal metabolic rate became normal, requiring an average of about five weeks, exhibited less reaction to the operation than ones operated on earlier. Since no patients have been found to become refractory to thiouracil and since most of them can continue with their work during the period of preparation for thyroidectomy, it is desirable to take time for satisfactory preparation.

We have recently attempted to reduce the amount of bleeding and friability of the thyroid gland by preparing the patients with iodide and thiouracil. Five patients who had received iodide were also given thiouracil. Seven patients not previously treated with iodide were given thiouracil for five or six weeks, during the last two or three of which iodide also was given. It was found that a remission of the thyrotoxicity could be obtained as readily as though only thiouracil was used, yet there tended to be somewhat less bleeding and friability of the gland. Occasionally the prothrombin time has been slightly increased, but this probably was a rare cause of bleeding.

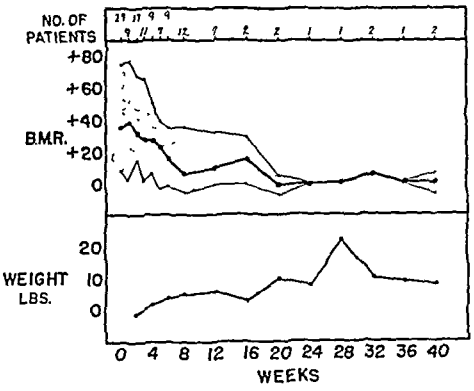

Fig. 5.—Response to thiouracil treatment of the basal metabolic rate and weight of 29 patients who had received iodide therapy for several weeks or more before thiouracil treatment was started. The delayed response in this group can be appreciated on comparing the changes with those in figures 1 and 2.

In the 59 cases treated by thyroidectomy, thiouracil was discontinued within about five days after the operation and most of the patients were permitted to go home two days later. Follow-up studies of all patients have shown that 1 developed myxedema and 2 had a recurrence of thyrotoxicity.

Anatomic and Chemical Changes in the Thyroid Gland.—The thyroid glands of the patients treated with thiouracil differed strikingly from those of patients treated with iodide. The histologic changes in the thiouracil treated glands varied somewhat, but there were rarely involutionary changes. There were usually considerable hyperplasia (fig. 7) of the acinar cells and many papillary projections. The colloid was scant and pale. Many acini contained no colloid, and occasionally none could be found in an entire microscopic section. Aggregations of collapsed acini appeared as solid sheets of cells. There was a slight increase in interstitial tissue. Lymph follicles with active germinal centers were not infrequently seen. The glands of 10 patients had colloid adenomas, and 5 had noncolloid adenomas. There was not much difference in the appearance of the thyroid glands of patients treated for several months and those treated for only three or four weeks. There was no correlation of the operative and postoperative course with the histologic changes in the gland other than that the more the hyperplasia, the greater was the tendency for bleeding.

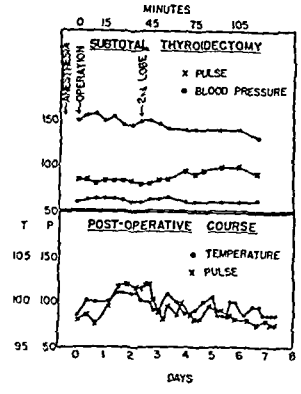

Fig. 6.—Operative and postoperative course of a patient who, as a result of thiouracil therapy, was in a remission from severe thyrotoxicosis. The thyroidectomy was one of the longest and most difficult technically of any of the 59 patients operated on and yet the patient's course was relatively smooth.

When iodide therapy was given before or during thiouracil treatment, usually more colloid and less hyperplasia was observed.

Determinations of the thyroxin content of the thyroid glands of patients treated with thiouracil, without iodide, showed that only small amounts were present. Thus the potentialities for a thyroid storm would appear to be reduced.

The content of thiouracil in the thyroid gland, determined in 37 cases, ranged from 5 to 29 mg. per hundred grams dry weight of thyroid and averaged 14. No relationship was observed between the concentration of thiouracil in the thyroid gland and (*a*) the preoperative, operative or postoperative course of the patients or (*b*) the histologic changes in the thyroid gland. Moreover, the concentration was not found to be proportional to the preoperative dosage. The administration of potassium iodide to patients receiving thiouracil did not seem to affect the concentration of thiouracil in the thyroid gland.

TOXIC REACTIONS TO THIOURACIL

Of the 152 patients treated 16 have developed untoward reactions to thiouracil, almost all of which have appeared during the first five weeks of treatment.

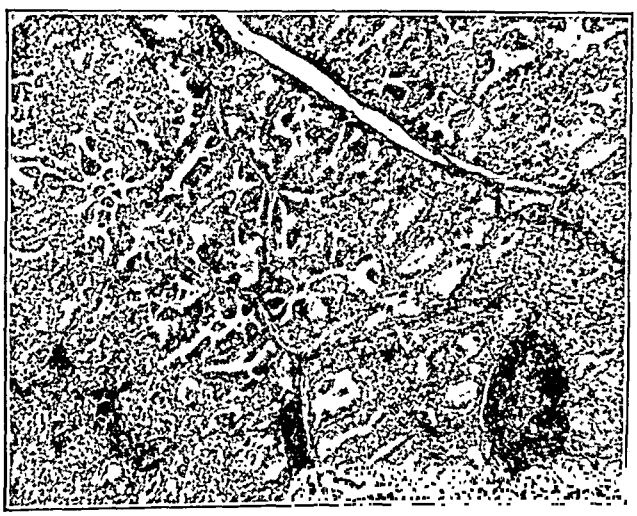

Fig. 7.—Section of a thyroid gland of a thyrotoxic patient who was treated with thiouracil for five weeks. The basal metabolic rate preceding treatment was plus 42 per cent of normal and at the time of thyroidectomy it was plus 4. Note the pronounced hyperplasia of the acinar cells, the very small amount of colloid present and the collapse of the acini. Nests of lymphocytes and one germinal center are present. Slightly reduced from a photomicrograph with a magnification of 80 diameters.

Two patients developed agranulocytosis, 6 edema of the legs, 5 urticaria, 4 morbilliform rash, 2 allergic arthritis, 2 vomiting, 2 fever, 1 diarrhea, 1 enlargement of the submaxillary salivary glands and 1 leukopenia without agranulocytosis. It is of interest to note that of the last 100 cases treated reactions have occurred in only 4, the difference being due in part to the use of dosages smaller than the ones used earlier. The only complication worthy of great concern is agranulocytosis. Both of our patients recovered after being seriously ill for several days. The patients with edema, rash, vomiting, diarrhea and enlarged submaxillary salivary glands were permitted to continue treatment with a reduction in the dosage of thiouracil. The other patients were either operated on soon after the appearance of the complications or were treated with iodide and thyroidectomy.

CONCLUSIONS

Thiouracil has been used in the treatment of 152 patients with thyrotoxicosis. It is highly effective in producing and maintaining a remission of the disease. Patients prepared for thyroidectomy with thiouracil experience less thyrotoxic manifestations before, during and after the operation than do patients prepared with iodide, but their thyroid glands sometimes bleed more. Supplementation of thiouracil with iodide therapy tends to decrease some of the technical difficulties of thyroidectomy. The only serious complication encountered is agranulocytosis, the actual frequency of which remains to be determined.

ABSTRACT OF DISCUSSION

DR. W. O. THOMPSON, Chicago: Three developments have occurred in the treatment of toxic goiter within the last few years. One is the demonstration of the interrelation of the pituitary and thyroid, and the dependence of thyroid function on pituitary function. I have recently applied that observation clinically and have been able to cure some cases of exophthalmic goiter by irradiation of the pituitary. Two other lines of attack have come forth. One is the administration of radioactive iodine and the other drugs like thiouracil and thiourea. Radioactive iodine and thiouracil attack the thyroid gland itself, just as surgical measures do. They probably do not attack the fundamental cause of toxic goiter, which many of us believe may reside outside the thyroid gland. Ultimately the method of treating toxic goiter may be an attack on its cause. That is why we were interested in the attack on the pituitary. Thiouracil does not have an important role as a method of preoperative preparation of the patient. With iodine and other measures we have been able to get the mortality rate in better clinics down to 1 per cent or less, and I doubt if it could be made much lower with the addition of thiouracil. About the only preoperative use is for patients in whom the disease cannot be controlled with usual measures. In such patients thiouracil may be a life-saving measure. The most interesting thing about thiouracil is the question Will it replace surgical procedures? It will take two or three years to determine what the precise status of this drug is. It will take that length of time to determine how serious the toxic reactions really are and in how large a percentage of cases the remission remains permanent after the drug has been discontinued. It would appear that a new day is dawning in the treatment of toxic goiter and that the days of the surgeon appear to be numbered. It may be that we shall not treat toxic goiter indefinitely with thiouracil or with these other measures that I have outlined, but we are on the way, and I am happy to see that the disease shows signs of being placed where it really should be placed, namely with the internists.

DR. ELMER C. BARTELS, Boston: The average person with hyperthyroidism responds well to iodine treatment, and operation can be done with little risk. There remains the severely toxic patient who even after ten to fourteen days of iodine treatment is a serious surgical risk. For these patients thiouracil is a most helpful drug. Studies at the Lahey Clinic have shown that thiouracil will reduce the basal metabolic rate to normal levels. Those patients who have had iodine before the administration of thiouracil have had a prolonged course. However, if treatment with thiouracil is continued, a normal basal metabolic rate will be reached. The dose of thiouracil used was 0.6 Gm. a day. The thyroid gland in the 25 patients observed did not decrease in size. The bruit and thrill persisted, and the gland remained in a hyperplastic state. The length of time required to obtain complete control of symptoms seems to be in direct relation to the elevation of the basal metabolic rate. In other words, it takes about one day for each degree of elevation in the basal metabolic rate. If thiouracil is used as a preoperative measure, it is essential that the drug be continued until a normal basal rate is obtained before operation is performed, since a reaction under treatment with thiouracil at a basal rate of + 40 is identical to that under treatment with iodine at a similar basal rate. However, if a normal basal metabolic rate is obtained, a normal anesthesia and postoperative course will follow. All our patients underwent subtotal thyroidectomy without the slightest anesthesia or postoperative reaction. The technical difficulty which the surgeon encounters

in removing the thyroid glands of patients who have received thiouracil is extremely great. On opening the skin, excessive bleeding occurs and the gland is found to be extremely soft and friable. It is difficult to isolate the recurrent laryngeal nerves and the parathyroid glands which our surgeons wish to see. We have been able to overcome this difficulty by giving iodine to the patients after the thiouracil has produced a nearly normal basal rate. Iodine involutes the gland so that three weeks after its administration subtotal thyroidectomy can be done without difficulty. Our pathologist, Dr. Shields Warren, has shown that the thyroid glands of patients treated with thiouracil are involuted with iodine treatment. We have had only two toxic reactions, which were manifested by fever. Since thiouracil produces hyperplasia, as does primary hyperthyroidism, the possibility of obtaining a cure from this agent seems to be unlikely. It was for this reason that we took a conservative attitude toward thiouracil, using it only as a preoperative measure. I should like to have Dr. Williams give his opinion as to this matter, since I fear the idea is developing that thiouracil has unquestionably curative properties.

DR. KARL E. PASCHKIS, Philadelphia: My experience in a series of about 30 cases is about the same as that of Dr. Williams; that, after effective and prolonged treatment, one can produce a clinical cure. Whether or not the drug will be a real cure is premature to tell. I agree with Dr. Thompson that it will take several years to solve that problem. The question whether the drug has any definite indication, aside from our curiosity to gain more experience, I would answer in the affirmative. I have had several cases in which I felt that this drug was needed and I would have been at a loss as to what to do without it. One group comprised cases in which the surgeons themselves felt that for one reason or another it was not safe to operate at all. Another group of cases in which there is a definite use consists of those which have been treated for a long time with iodine. Every one of us has seen cases which have been treated for months or for a year with iodine, apparently at one time or another with good response. Then the practitioner has continued giving them iodine, and they have come to the hospital with a high basal metabolic rate, with full-fledged thyrotoxicosis and utterly irresponsive to further iodine. These cases have responded slowly but safely to thiouracil, and we were then able to subject them to surgery or to continue medical treatment. In such cases I believe that there is already today a definite place. I have observed toxic reactions in 4 out of 30 cases. There was no serious toxic reaction. There was no agranulocytosis. The reactions consisted of fever, drug rash, swelling of the joints and, in 1 case, a transient jaundice. All of these, including the jaundice, disappeared twenty-four hours after treatment was discontinued. At least 3 out of the 4 were in some way sensitized, so that with renewed attempts to treat them they reacted with toxic manifestations to minimal doses. It was necessary to discontinue treatment. One of the problems is to find a way of desensitizing such patients. The other problem is of a chemical nature, whether a similar compound might be found which is less toxic. I am rather skeptical, because these toxic reactions apparently are a question of drug sensitivity, and in any active drug we shall always find cases which are sensitive.

DR. RULON W. RAWSON, Boston: At the Massachusetts General Hospital we have used thiouracil primarily to prepare thyrotoxic patients for thyroidectomy. Like Drs. Williams and Clute, we have observed the drug to be an effective agent in causing a fall in the basal metabolic rates and clinical improvement of thyrotoxic patients who have previously had no iodine. Previously iodine treated patients responded to the drug, but at a much lower rate. Likewise patients with toxic nodular goiters respond slowly. We think that this is due to the nature of the drug's action. By determining the ability of thiouracil-ized thyroids to collect radioactive iodine, we have demonstrated that the drug acts by blocking the iodination of the thyroid hormone. Ergo no fall in the rate of metabolism is evident until the stored hormone has been used. We feel that the advantages of thiouracil over iodine in preparing thyrotoxic patients for thyroidectomy are (1) that if the drug is administered long enough the rate of metabolism can be lowered to normal or lower, thus giving the surgeon a nontoxic goiter to ablate and (2) that the postoperative course of patients prepared for thyroidectomy with thiouracil is much milder than that observed in comparable patients prepared with iodine. In 10 per cent of our cases the vascularity of the gland has proved to be a surgical hazard. Patients prepared with thiouracil and then treated with added potassium iodide have been observed to have less vascular and less hyperplastic thyroids, which as such have been less difficult for the surgeon to remove. I am in disagreement with Dr. Williams's statement that these glands become smaller. We have observed that the thyroids of patients treated with thiouracil become softer. As such they might give an erroneous impression of being smaller. Indeed by determining the thyroid mean cell height of biopsy specimens taken from thyroids of 5 patients before administering thiouracil with similar examinations of the operatively removed thyroids after preparation with this agent, we have demonstrated that the exhibition of this drug does cause an increase in thyroid hyperplasia. We have been concerned by the number of toxic reactions observed in patients receiving thiouracil. We have seen toxic reactions in 15 per cent of our cases. Some of the toxic effects that we have observed have been diffuse lymphadenopathy, morbilliform rash, drug fever and leukopenia. We have not observed agranulocytosis. A few of the cases of agranulocytosis observed by other groups have been fatal. A number of our patients have had dental abscesses develop or become activated while taking the drug. It is my impression that this drug is more effective than iodine in preparing thyrotoxic patients for thyroidectomy. I do not believe that the evidence is adequate to conclude that thiouracil is a medical cure for thyrotoxicosis. A medical cure for thyrotoxicosis will, I think, have to attack the primary pathologic physiology of the disease. I do not believe that thiouracil does that any more than surgical removal of the thyroid does. However, studies of the disease made possible with this new agent have thrown considerable light on the normal and abnormal physiology of the thyroid and may thus contribute to the discovery of a physiologic cure of this malady.

DR. ROBERT H. WILLIAMS, Boston: In the use of this drug, as with thyroidectomy, we are not getting at the basic difficulty of thyrotoxicosis. I agree with Dr. Bartels that it is important to take time in getting the patient well prepared for thyroidectomy. Thus far we have no evidence of "thiouracil escape" or thiouracil resistance. In fact, a large proportion of our patients were permitted to perform their regular activities of life, and therefore the prolongation of treatment did not cause a handicap. Dr. Bartels asked that I express an opinion in regard to the possibility of medical cure, using thiouracil. I do not feel as though we have enough scientific evidence really to venture a guess in that regard. In reply to Dr. Rawson's comment about the discrepancy of his results and ours, concerning a decrease in the size of the thyroid gland, the statement which I made dealt with patients who were treated for more than four months with thiouracil and, if I recall correctly, most of his cases have been treated for less than this period of time.

Vicarious Expression in the Neuroses.—Every neurosis is more or less of a flight from reality. Whenever the stress of life is too strong one may find refuge in fantasy. The conflict between the inner emotions and the crushing realities of life often finds vicarious expression in the neuroses. The process is unconscious and, therefore, is not amenable to reason or logic. One cannot convince or be convinced. The emotions involved are too primitive. One may rationalize one's behavior, one may give reasons which seem to explain, but, in reality, they do not touch the root of the problem. But the neurosis serves a useful purpose. It acts as a safety valve for the emotions. True, it is an infantile way out of a difficulty, but it is none the less an attempt at an adjustment to reality.—Wechsler, I. S.: The Neurologist's Point of View, New York, L. B. Fischer, 1945.

THE MANAGEMENT OF EXTENSIVE SCALP DEFECTS IN CRANIO-CEREBRAL INJURIES

MAJOR S. G. BALKIN
MAJOR C. E. DOWMAN
AND
CAPTAIN W. W. KLEMPERER
MEDICAL CORPS, ARMY OF THE UNITED STATES

Craniocerebral injuries present themselves, at times, as both a neurosurgical and a plastic problem the solution of which should be accomplished at the initial operation. Intracranial injuries not infrequently are accompanied by partial evulsion and devitalization of the scalp. Probably more scalp tissue is excised during the débridement than is lost by evulsion; however,

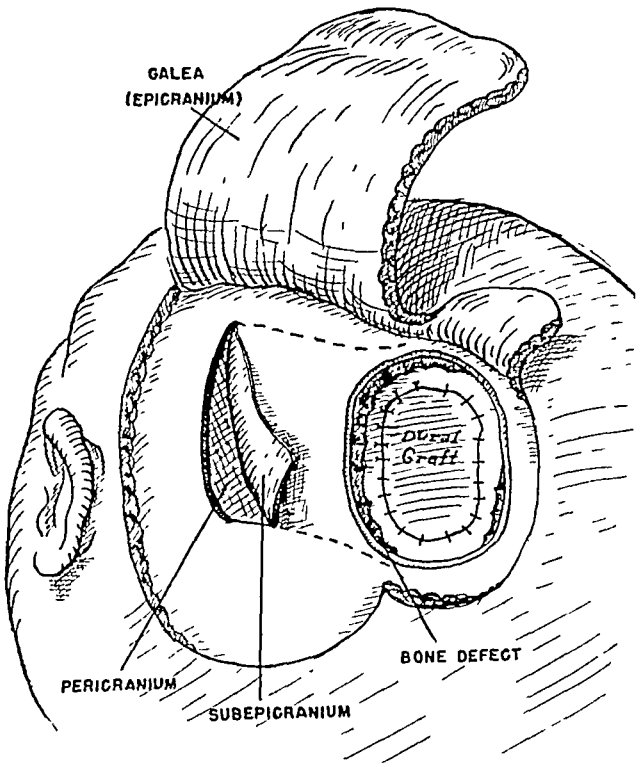

Fig. 1 (case 3).—Elevation of scalp flap. Subepicranial hinge flap outlined and being raised. Dural graft has been sutured into position.

despite the notorious viability powers of the scalp one can compromise but little when dealing with partially or completely devitalized scalp tissue. The size of the resultant scalp defect ceases to influence the thorough débridement when rather simple plastic procedures are available.

The inelastic character of the scalp is due to the short fibrous septums, which form an inelastic subcutaneous layer and which bind the skin firmly to the galea. However, beneath the galea, the subepicranial space is filled with loose connective tissue. Any form of relaxing incision in the scalp which reaches only as deep as the galeal layer can be of no use, yet even those which penetrate into the subepicranial space allow at best only slight mobility of the surrounding scalp. This is especially true over the occipital and parietal regions; however, over the frontal and temporal areas the scalp is less firmly attached, and small defects may be closed by direct approximation of the skin edges, utilizing relaxing incisions, tripod and the like. Further, owing to the pull of the occipitofrontalis muscle, defects closed in an anteroposterior direction can be brought together with less tension than similar ones closed in the opposite plane.

However, extensive scalp defects are best repaired by sliding flaps obtained from the borders of the defect; nothing can be gained by undercutting and stretching the scalp. Usually one single pedicle flap of sufficient size can be obtained to cover the defect adequately. Occasionally it may be necessary to rotate two single pedicle flaps when availability of scalp tissue is limited. If, for any reason, the blood supply to the scalp is questionable or it is not feasible to make the base of the flap of sufficient width, in order not to jeopardize the result a double pedicle flap should be utilized. Often the scalp lacerations will extend beyond the borders of the defect, and these will in no small way influence the size, shape and number of flaps to be used.

The covering flap, or flaps, should be so designed as to fill the defect without tension and should extend beyond the borders of the bony defect for a considerable distance. The flap can be outlined and quickly raised by blunt dissecting through the subepicranial space with little bleeding encountered in this space. The bleeders above the galea are caught as usual, but those on the flaps are not coagulated nor are ties applied. There is little tendency for the flap to bleed once it has been raised.

At this point, with the scalp flap raised, subepicranial tissue becomes available lateral to the bony defect. A sufficiently large flap of this tissue may be outlined with the base at the margin of the defect and tipped over to cover it (fig. 1).

The scalp flap is now sutured into the defect, covering the subepicranial graft, a two layer closure being used. The drain necessary to prevent the collection of blood or cerebrospinal fluid beneath the flap is placed preferably through a stab wound at some distance from the suture line.

The puckering of the inelastic scalp which occurs at the point of rotation of the flap is unavoidable and in time "irons" out quite well.

The donor site of the flap with its large surface of subepicranium exposed is now covered with a split skin graft carefully sutured into position, the suture ends being left long and to be used as ties later. Accurately fitted over this free graft are several thicknesses of petrolatum gauze and layers of dry gauze, which extend considerably above the surface of the scalp. The long suture ends are now tied over the gauze with moderate tension (fig. 2). This produces, to all intents and purposes, a stent with sufficient pressure over the graft (fig. 3). No additional pressure dressing is necessary. As a result, the dressings which cover the flap and drain can be removed daily if necessary without disturbing the graft. All sutures and the stent are removed on the fifth or sixth postoperative day. At first removal the area covered by the split graft appears as a deep hole, but with contracture of the skin this will gradually fill up (fig. 4).

REPORT OF CASES

CASE 1.—*History*—The wound, received before 1 p m on Nov. 29, 1943, was caused by a high explosive artillery shell fragment, which avulsed the right frontal scalp and drove bone fragments into the right frontal lobe (fig. 5 *A*). The patient was seen at the collecting station at 1 o'clock, where his wound was dusted with sulfanilamide and dressed and a unit of plasma injected. He reached the clearing station at 2·40, the evacuation hospital at 3 o'clock.

Examination—On admission to this evacuation hospital he was comatose, the pulse rate was 140, the blood pressure was 100/78, he was in moderate shock and bleeding moderately from his wound He was quite uncooperative, but gross neurologic testing revealed no other abnormalities Five hundred cc. of plasma slowed the pulse to 100, the blood pressure was 120/74, and 500 cc. of blood improved him so that he could be x-rayed and operated on X-ray examination showed a large defect in the right frontal bone with fractures involving most of the skull, and bone fragments driven into the frontal lobe

Operations (C. E D)—From 11 p m of the 29th till 2 a. m of the 30th under pentothal sodium and local anesthesia the scalp was debrided narrowly, the loose bone fragments were removed, and the remaining bone edges were smoothed. Several radiating fracture lines were noted About 75 Gm of damaged brain plus indriven bone and hair was sucked away and the clean bed was checked for complete hemostasis The only tissues available for closure were the temporal muscle, the pericranium and some subepicranium. These structures were approximated, with the intent of doing a plastic closure later (fig 5 *B*) Sulfanilamide crystals and petrolatum gauze dressing were applied By the next morning the closure had broken down with cerebrospinal fluid leakage The patient was still confused, and movements of the left arm were definitely weaker.

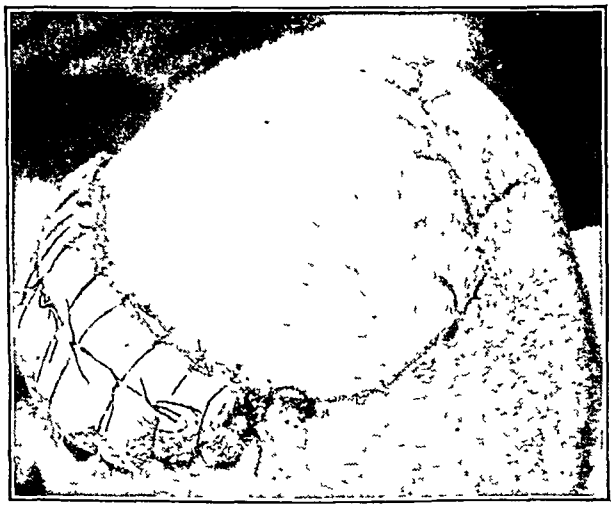

Fig. 2 (case 3)—Six days after operation, showing scalp flap healed and stent over skin graft maintaining pressure tied over by sutures

Twenty-four hours later, between 1 and 2 30 a m. of December 1, as it was felt that covering of the exposed brain was necessary, a local anesthetic was given and a large double pedicle scalp flap was outlined posterior to the defect It was undercut and raised but could not be slid forward sufficiently to reach the anterior edge of the wound (fig. 5 *C*). In view of the scalp laceration, which extended posteriorly from the defect and traversed approximately one third of the way across this flap, it was felt that the use of two single pedicle flaps would be more advisable, utilizing this laceration (fig. 5 *D*). These two flaps were raised by dissecting through the subepicranial space and rotated forward They were sutured into position in two layers, and the drain was placed through a stab wound anterior to the defect (fig. 5 *E*). The exposed donor site of the flap was covered with a split skin graft, pressure for the graft being obtained by tying the long suture ends over a petrolatum and dry gauze stent.

Postoperative Course.—By December 6 all sutures were removed, the flaps had healed well and the skin graft had taken However, the patient was still confused and incontinent, the postoperative course being rather stormy. He went downhill rapidly and died December 11. The cause of death was a purulent meningitis.

Fig 3 (case 3)—Stent after removal

CASE 2—*History*—On Dec 8, 1943 at 4 p m. high explosive artillery shell fragments inflicted a large lacerated wound over the bridge of the nose, extending upward with an avulsion of the skin over the left side of the forehead (fig. 6 *A*). The patient reached the aid station at 4 15, where he was dressed and given a half-grain (0 032 Gm) dose of morphine; he passed through the collecting station at 5.10 and the clearing station at 6·45, where he was given 2 units of plasma.

Examination—On admission to the evacuation hospital at 8 45 he was mentally confused. A small amount of damaged brain oozed from the wound There were no gross neurologic signs. His blood pressure was 104/70, pulse rate 64 He was quite cold from exposure and was given 500 cc of blood and 500 cc. of plasma preoperatively. X-ray examination showed a compound comminuted fracture of the left supraorbital area with bony fragments displaced back and to the right; there were several foreign bodies of the left frontal and orbital areas

Fig 4 (case 3)—Entire defect covered six days after operation

Operation (C E. D.).—This was performed under pentothal and local anesthesia between 3 and 6.15 a m December 9. The patient was given 1½ grains (0 1 Gm) of phenobarbital

at 9:30 p. m. and ⅛ grain (0.01 Gm.) of morphine and 1/150 grain (0.0004 Gm.) of atropine at 2 a. m. December 9. The skin and galea were radically debrided, and the loose bone fragments of the orbital rim and the roof and mucosa of the frontal sinus were removed. The loose left nasal bone was left in situ. The nasal mucosa exposed on removal of the mesial bone chips was unruptured and was not disturbed. The first branch of the trigeminal nerve lay in the wound and was injected with procaine hydrochloride. A small dural tear over the convexity of the frontal pole was enlarged, and about 10 Gm. of damaged brain was sucked out, bleeding being controlled by the electrocautery. The dura was closed with interrupted 000 silk sutures. Five Gm. of sulfanilamide powder was now sprinkled into the wound and a half-inch petrolatum gauze pack laid into the space between the dura and the remaining frontal bone, being led out through a lateral stab wound.

Operation (S. G. B.).—A large scalp flap, 8 by 8 cm., was raised posterior to the defect, with its base on the right side (fig. 6*B*). The flap was rotated forward into the frontal defect and sutured in two layers. A drain was placed through a stab wound lateral to the suture line (fig. 6*C*). The

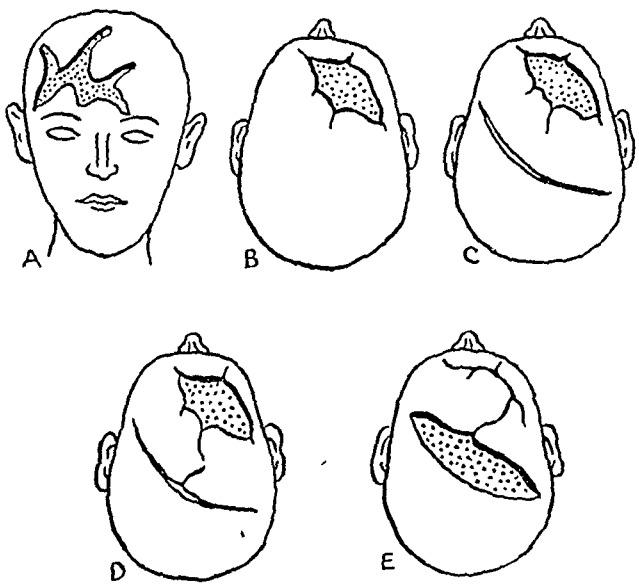

Fig. 5 (case 1).—*A*, outline of scalp defect before débridement. On this as on all subsequent figures, with the exception of figure 1, the outline of the bony defect is omitted for purposes of simplification. However, it extended beyond the borders of the undebrided scalp wounds in all 3 cases. *B*, scalp defect debrided, and partial closure of defect. *C*, double pedicle flap outlined and raised. *D*, two single pedicle flaps outlined, long posterior laceration being utilized. *E*, rotation of flaps forward. Flap donor site ready for split skin graft.

donor site of a flap was covered with a split skin graft in the manner as described previously.

Postoperative Course.—The drain was removed December 10 and all sutures were removed by the sixth postoperative day. The patient made an uneventful recovery and was evacuated to the rear in excellent condition.

CASE 3.—*History.*—A gutter wound involving the scalp and underlying bone in the left anterior superior parietal area was inflicted by a high explosive shell fragment, 2 p. m., April 19, 1944. Brain was herniating through the defect and was bleeding freely. The wound was dusted with sulfanilamide powder and dressed at the aid station at 4:25 p. m. The patient passed the clearing station at 5:30 and arrived in fairly good condition at this evacuation hospital at 7:30, almost six hours after the injury.

Examination.—The patient was aphasic but tried to cooperate. The blood pressure was 118/44, pulse rate 76, respiratory rate 20. He had a complete right flaccid hemiplegia, absent superficial reflexes, normal deep reflexes on the left and diminished deep reflexes on the right side. Plantar response was normal on the left, suggestive extensor on the right. The patient's head wound was located just left of the midline in the anterior superior parietal region. The scalp defect was about 8 by 10 cm. in size, covered by a bluish torn and partially devitalized scalp flap. Devitalized bleeding brain herniated through the underlying bone defect measuring about 6 by 6 cm. X-ray

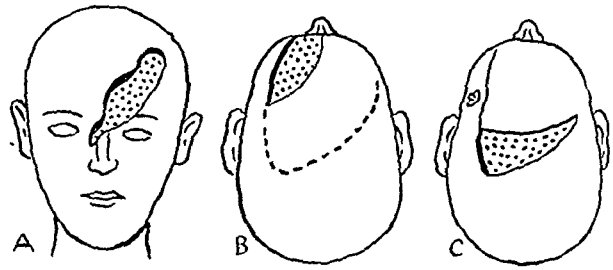

Fig. 6 (case 2).—*A*, debrided scalp defect. *B*, single pedicle flap outlined. *C*, pedicle flap rotated forward with drain through stab wound. Flap donor site ready for split skin graft.

examination showed a gutter type of cranial defect measuring 6 by 12 cm. in the frontoparietal region just left of the sagittal suture line.

Operation (W. W. K.).—Preoperative medication consisted of ⅙ grain of morphine and 1/150 grain of atropine at 12:30 a. m. April 20. The operation was performed with pentothal and local anesthesia between 12:50 and 4:50 a. m. The scalp wound was completely debrided, all devitalized or "doubtful" scalp being removed (fig. 7*A*). The underlying bone defect was smoothed out and enlarged until the frayed dural edges presented. Devitalized cerebrum containing hair and bone fragments was washed and sucked out. A good number of severe bleeders from the medial aspect of the wound were controlled with the electrocautery. The resulting cerebral defect was about 6 by 6 by 4 cm. in size. Following hemostasis and repeated lavage of the entire field, 2 Gm. of sulfanilamide was dusted into the cerebral defect. The large dural defect was closed with a free subepicranial graft.

Operation (S. G. B.).—A large scalp flap, about 7 by 9 cm., was raised over the left temporoparietal region, with the base anterior (fig. 7*B*). The bony defect was then covered by raising a flap of the exposed subepicranium bordering the bony defect, hinged over this and sutured into position (fig. 1). The scalp flap was now rotated over the smaller sealing flap and sutured into position in two layers (fig. 7*C*). A drain

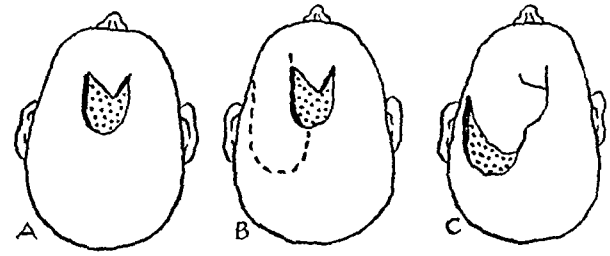

Fig. 7 (case 3).—*A*, debrided scalp defect. *B*, single pedicle flap outlined. *C*, scalp flap rotated medially and donor defect ready for covering with split graft.

was placed in this instance through the suture line. The large defect caused by raising the flap was covered by a split skin graft in the manner described.

Postoperative Course.—The drain was removed within forty-eight hours, and all sutures were removed on the sixth postoperative day. The flap had healed well and the skin had taken (figs. 2, 3 and 4). The patient made an uneventful recovery and was evacuated to the rear in good condition, though still hemiplegic and just starting to regain his speech.

COMPLICATIONS IN THE SURGICAL TREATMENT OF CARCINOMA OF THE LARGE BOWEL

W. WAYNE BABCOCK, M.D.
AND
HARRY E. BACON, M.D.
PHILADELPHIA

In 712 operations for colonic cancer we have found such operative complications as atelectasis, pneumonia, parotitis, coronary occlusion, pulmonary thrombosis and phlebitis infrequent, or at least not relatively increased. Using spinal anesthesia with associated infusion or transfusion and oxygen inhalation, shock has been rare and in no case of such intensity as to prevent the completion of the operation. No serious anesthetic or diabetic complication has occurred. In the postoperative period one elderly man twice developed precordial oppression when 180 cc. of 5 per cent glucose solution had been given; the second time permanent cardiac arrest occurred suddenly when 220 cc. had been given.

OPERATIONS

In our series the operations used have undergone considerable evolution. Patients with such advanced peritoneal involvement that resection is out of the question are closed with layer sutures of alloy steel wire and encouraged to be out of bed two or three days after the operation and to return home within a week. For other patients with advanced ineradicable cancer palliative permanent colostomy has largely been replaced by a palliative one stage resection of the diseased segment of bowel and restoration of intestinal continuity, either by end to end anastomosis or a pull through type of operation using a perineal outlet, if possible with utilization of the anal sphincters. This has pleased the patient and his family and has reduced our hospital morbidity and mortality, although it has increased the total mortality of our primary resections. Formerly the patient with advanced local and metastatic growths had a "palliative" colostomy and then was considered such a burden by his relatives that often they refused to remove him from the hospital, where he remained until he died. Now most patients, even with very advanced growths in the liver, are treated by means of resection and are able to leave the hospital within two weeks. As a rule they look and feel much improved after the resection, are able to care for themselves and may be able to do considerable work. From observing these patients it is apparent that the majority suffer more from the toxic necrosis, ulceration and hemorrhage in the bowel than from the metastases in the liver. Even after a previous palliative colostomy, decided improvement may follow the radical operation. A woman, left with a colostomy after two futile attempts at excision of the rectum, was active for three years after removal of the rectosigmoid and transfer of the colostomy to the perineum. If the carcinoma has been of the obstructive type the obstruction rarely returns in complete form at the point of anastomosis during the lifetime of the patient. Duration of life with secondary carcinoma of the liver is variable but not infrequently may continue two or three years, throughout most of which time the patient may consider himself in good or fair health.

WOUND COMPLICATIONS

Abdominal wound infection and dehiscence are especially to be feared after operations for cancer of the colon. We have found oblique muscle-splitting incisions of great advantage. They may be used for carcinoma of any part of the large bowel. For the sigmoid and rectum the incision is placed about 3 cm. above and parallel to the left inguinal ligament. The external oblique is split, and the internal oblique and transversalis muscles are partly divided. If more room

Read before the Section on Gastro-Enterology and Proctology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

is required the incision is extended to the right through the rectus sheath and, if necessary, the rectus and pyramidalis muscles. For the cecum or the ascending or descending colon an incision is made from the tip of the eleventh rib to a point about 4 cm. below the navel; for the colon and its flexures, from the ninth rib to a point about 3 cm. above the umbilicus on the side of the lesion. Usually the anterior and posterior sheaths of the rectus are divided and the rectus muscle is retracted, the fibers of the external oblique being split. If the cancer is attached to the abdominal wall, infiltrated portions are freely resected and removed with the tumor. If there is a medial scar from a previous abdominal operation, this is excised to avoid the formation of a second scar. For twelve years alloy steel wire sutures have been used, and to a large degree fine alloy steel ligatures, for the abdominal wall.

No eventration has occurred in our series, and unless an infected area has been entered during the operation, primary union and very satisfactory scars are the rule. In case of contamination one or more sump drains are used in the peritoneal cavity, and the outer layers of the wound are drained. After adoption of our suggestion to use wire sutures instead of catgut for the abdominal closure, Dr. Thomas Jones of the Cleveland Clinic reported a reduction in wound infections from 27 per cent to under 1 per cent.[1] With the onset of postoperative infection the wound is laid freely open, and frequently renewed gauze dressings wet with 1:500 to 1:1,000 bromine solution are applied. This also is a useful dressing in spreading pyoderma and is an excellent deodorant for necrotic wounds and fecal or urinary fistulas. It does not discolor bed linen as does potassium permanganate. From invasion of septic areas we have had very virulent peritoneal and abdominal wound infections occur despite the free local use of sulfonamides.

SEPTIC PERITONITIS

Septic peritonitis from an ulcerating, necrotic carcinoma of the colon is one of the great hazards in its operative removal. The brittle, infiltrated bowel may break open or pull in two during attempts at liberation. The stomach, urinary bladder, small intestine or gallbladder may contain feces and pus from a fistula, or there may be a communicating abscess in the peritoneum or abdominal wall. To expect sterilization by daily irrigation through a defunction-producing colostomy is chimerical, although it may greatly reduce the gross contamination. Like others we have found increase in operative difficulties and mortality from stage procedures. The preoperative administration of succinylsulfathiazole or phthalylsulfathiazole by mouth at present seems of value. We have attempted to sterilize intestinal contents and mucous surfaces about rectal carcinoma locally before operation by irrigation and packing with gauze wet with germicides, using mercurial, strong hypochlorite solutions or tincture of iodine. Of these we prefer a 3.5 per cent tincture of iodine. If an abscess has formed, an attempt is made to remove it intact with the attached section of colon, which usually is feasible if the abscess involves the abdominal wall. With a fistula into a hollow viscus an aseptic *en bloc* removal is preferred. Adherent perforated loops of bowel, bladder and stomach are resected if possible by cautery between clamps. Eight to twelve clamps may be used, and it is desirable to have various sizes of clamps without handles, of the modified de Martel type, available. With them we have found it possible to do a complicated resection without leakage or soiling, using what one of us has previously described as the single clamp method for each final anastomosis.[2]

DRAINAGE

During operation leakage is to be feared, especially from an advanced carcinoma, because of the ulcerated, thinned and brittle intestinal wall, which may perforate, or from outlying areas of infection in lymphatic and other tissues which may be entered in the liberation of the diseased bowel. By avoiding traction on adjacent bowel but applying it rather to peritoneal or mesenteric folds beyond the growth, the danger is reduced. An empty bowel is much safer than one obstructed and distended. Free drainage, however, plays a very important part in the prevention of peritonitis. During the first three days after resection of the large bowel there usually is an exudate of 300 to 800 cc. of blood and serum into the cavity. This is a culture medium so often contaminated as to constitute, if not removed, a great hazard. Our earlier operations with inadequate drainage had a mortality of 16 per cent or more. The present low mortality of the Miles operation we consider largely dependent on the massive drain of rubber and gauze or other material introduced through the perineal wound. The mortality of our pull through type of proctosigmoidectomy fell from about 16 to around 6 per cent with the use of large curved perforated glass or rustless steel tubular drains introduced along the sacrum. If free dependent drainage is not used we introduce through the abdominal wound or a separate suprapubic stab one or more perforated tubular drains of rustless steel, 8 mm. in diameter, with an inner continuously acting suction tube. Beginning with nearly pure blood, the material removed gradually becomes more serous and finally after a number of days may cease to drain, when it is removed. Differing from rubber and plastic drains, which provoke encasing adhesions, this type drains the general peritoneal cavity for four or more days and gives early evidence of hemorrhage, of leakage or of the onset or subsidence of an ileus. Ileus is characterized by a sudden great increase in the amount of serum aspirated from the peritoneum. In several cases in which fecal leakage has occurred after anastomosis these drains have prevented diffusion in the cavity and led to the formation of a narrow fistulous tract which has closed spontaneously.

COLOSTOMY OR APPENDICOSTOMY

Colostomy or appendicostomy is useful for the relief of obstruction due to a carcinoma of the left colon or as a complemental operation in resection of the bowel. The Devine defunctioning procedure may be dangerous when the transverse colon is tense and thinned from distention by fecal material. It then is difficult to suture the arms of the loop together without tearing or puncturing the bowel or to exteriorize the ends of the divided bowel without contaminating the subcutaneous fat. The clamps devised may not be suitable for the individual patient; sinuses or fistulas may persist from the two segments of bowel left implanted

in the abdominal wall, and the final closure may greatly prolong the patient's hospitalization. As a rule we prefer a simple appendicostomy or cecostomy. The appendix and mesoappendix are pulled through a small stab wound at McBurney's point and a 14 or, preferably, a 16 F. rubber catheter passed into the cecum and tied in. The mesoappendix remains attached to nourish the portion of the appendix within the abdominal wall. The catheter should be tied in with two ligatures, anchored by tying them over dental cotton rolls, and then tested by irrigation to prove its position within the cecum. Unless carefully anchored and viable, the section of appendix may slip back into the abdomen. For decompression the colon may be frequently irrigated with 1:10 solution of hydrogen peroxide. After the appendix has adhered in the wound it may be dilated by the daily introduction of catheters of increasing size until, if desired, a 26 or 28 F. is in place.

If the appendix is absent or stenosed, a cone of cecum is pulled through the stab wound and anchored by forceps. Two concentric purse-string sutures are inserted, within which a catheter is introduced, tied in the cecum and the cone of cecum securely anchored by tying the ends of the purse-string sutures over dental cotton rolls.

THE ANAL ORIFICE

In the pull through operation a functional anal orifice is desirable. Our experience has shown that the following features are important to avoid complications:

1. The carcinoma should be at least 5 cm. (2 inches) above the anal ring and without involvement of the pelvic floor. We are indebted to Gilchrist and David, Coller, Kay and McIntyre—as well as Grinnel—for showing that the lymphatic spread of rectal and sigmoid cancer is upward and not toward the perineum and that rarely is there microscopic evidence of malignant cells more than 3 cm. below the growth.[3] With carcinoma of the anus the lymphatic spread is around the inner side of the groin to the medial inguinal lymph nodes, which should be excised.

2. The portion of sigmoid brought to the perineum should have adequate blood supply. This is proved in the abdominal part of the operation by the pulsation of arteries, or, if the blood pressure is low and the vessels are covered by fat, by incising vessels on the bowel after interrupting the blood supply from the anal side.

3. The sphincters always should be divided on one side and the sigmoid should lie so loosely in the anal canal that the finger can be introduced beside it. In every case in which we have brought the sigmoid through a dilated or divulsed sphincteric ring the muscles have contracted, cutting off the circulation, with resulting gangrene of the sigmoid. In such a case, if the anus is not promptly and freely opened, fetid exudate accumulates in the pelvis, with dangerous infection.

4. An end to end anastomosis by suture between the end of sigmoid and the perineal skin or the anorectal mucosa should not be attempted, nor should sutures be used to unite the sigmoid with surrounding perineal structures. The incidence of destructive infection with loss of sphincters and necrosis and retraction of sigmoid were so high in experiences before 1930 that we have since allowed the sigmoid to lie loosely in the perineal opening and projecting from 6 to 9 cm. A 26 or 28 F. rectal tube is tied into the projecting sigmoid, with two heavy ligatures. Several times secondary hemorrhages have occurred from the end of the sigmoid, necessitating an additional ligature. We mention this, as interns usually think the bleeding comes from the perineal wound, which they may tear open and pack unnecessarily. About the sixth day the rectal tube sloughs out at a time when the wound, protected from contamination, has soundly healed. A day or two later the protruding bowel may be removed by a tonsil snare or even with the perineum.

Our first method was to withdraw and exteriorize the large loop of liberated rectum and sigmoid through a median incision running from the margin of the anus to the right side of the base of the coccyx. Dressings were then applied, the purse-string suture removed from the anus, and the loop of bowel cut away and rectal tubes tied in the rectal and sigmoid ends. Later the partitions between the anus and rectal end and the rectal end and sigmoid were divided. For a few patients a later plastic reconstruction was made to form an anal ring. But about 85 per cent of the patients found they could go without a protective pad most of the time, provided they took a quickly acting laxative or enema every second or third day, and felt that a further operation was unnecessary. About 10 per cent without the aid of sphincters are not troubled by soiling provided a nonobstructing opening is maintained. It was necessary to open the perineal wound freely if infection developed. The technic was later changed to a posterior medial perineal incision, the rectum being divided above the sphincters, which were split posteriorly, the protruding sigmoid laid in the anal groove and a large glass drain introduced along the sacrum. The projecting sigmoid was burned off flush with the perineum about one week after the operation. This gave a fairly satisfactory result, but infection in the perineal wound had too high an incidence. A recent modification has been to depend on careful packing of the rectum with 3.5 per cent tincture of iodine gauze, and the preoperative use of succinylsulfathiazole for sterility; to divide the rectal mucosa just above the sphincters, to place the withdrawn sigmoid in the split anal ring, and to close the deep pelvic floor and skin very loosely about the bowel with deep and superficial wire sutures. For drainage an 8 mm. sump drain is introduced through the abdominal incision or a stab wound to the pelvic floor, with continuous night and day aspiration, as long as appreciable quantities of blood and serum are withdrawn. With this method a normal appearing functional anus has been obtained with the fewest urinary or sexual complications. With carcinoma of the anus, this and the pelvic floor are freely excised.

For advanced lesions with infected areas invaded during the liberation, very free open drainage should be employed.

In the last 250 consecutive operations for cancer of the large intestine the operability rate has been high, 96 per cent. No palliative colostomy has been used. Forty-one patients (4 with lymphopathia) have

3. Coller, F. A.; Kay, E. B., and McIntyre, R. S.: Regional Lymphatic Metastases of Carcinoma of Stomach, Arch. Surg. **43**: 748 (Nov.) 1941. David, V. C., and Gilchrist, R. K.: Lymphatic Spread of Carcinoma, Ann. Surg. **108**: 621, 1938. Grunel, R. F.: Grading and Prognosis of Carcinoma of Colon and Rectum, Ann. Surg. **109**: 500, 1939.

had a permanent colostomy usually made by another surgeon transferred to the perineum or eliminated by excision, intestinal resection and end to end anastomosis. The use of end to end anastomosis has been extended to carcinoma of the sigmoid and upper two thirds of the rectum. By leaving an intact pelvic floor and anus, the bladder and sexual complications incident to the Miles or other abdominoperineal resections are largely avoided. Advanced hepatic metastasis and localized visceral invasion have not contraindicated radical measures, and with single stage procedures the patient usually is able to be out of bed by the seventh or eighth day and to return home by the fourteenth day after operation.

COMPLICATIONS

The Mikulicz, Block or Paul operation has complications which should be understood clearly. It is performed in stages, the completion of which usually requires several months. Even if the patient returns to his home between stages the total period of hospitalization is longer than required with other methods. It usually leaves a weak abdominal scar or hernia. Wound contamination from the exteriorized bowel is fairly frequent. It is chiefly used for removal of the sigmoid but is the least radical of the methods of sigmoidectomy and more subject to local recurrence in the bowel, abdominal wall or mesentery than any other operation. In the loop of bowel to be liberated and exteriorized, 5 to 8 cm. of the arms of the loop left within the abdomen are sutured together to form a spur or partition, 2 to 8 cm. to reach through the abdominal wall and 4 to 8 cm. to project above the surface of the skin. Thus a total of 22 cm. in a thin patient to 48 cm. of bowel and attached mesentery in an obese person may be required for the proper exteriorization of the loop of cancerous bowel, all of which additional bowel and omentum could be removed in a resection with end to end anastomosis. These limitations explain the frequency of recurrences of carcinoma in the abdominal wall, arms of the loop or the underlying mesentery. We have treated these recurrences by a wide *en bloc* excision of the arms of the loop, mesentery and overlying attached abdominal wall, but often the disease had then spread beyond the range of complete operative extirpation. In attempting to remove more of the distal sigmoid or rectum we have exteriorized the lower segment under tension in the grasp of a clamp. In several cases the bowel sloughed loose from the clamp and slipped back into the pelvis, for which free drainage is necessary, a defunctioning transversostomy desirable, to be followed by additional procedures to establish the continuity of the bowel. If the mesenteric sides of the arms of the loop are apposed, the clamp placed on the spur may then cut off the blood supply, with necrosis and perforation. Tubes of glass or rubber introduced through the abdominal wall also may produce necrosis and perforation. We have had glass angle tubes made with bulbous ends to be tied into the bowel and rest above the surface of the wound to avoid the perforation within the abdomen, which may occur with a Paul or Mixter tube. When the arms of the loop have not been sufficiently united by suture, a loop of small bowel may slip within the jaws of the crushing clamp, and a secondary small intestinal fistula may follow. For this the wound should be reopened promptly, and the intestinal orifice closed by suture. This occurred once in our series, following a Mikulicz resection of the transverse colon, with recovery. At present, because of these various objections, we employ the more radical and much more satisfactory single stage resection with aseptic end to end anastomosis for all carcinomas of the large bowel above the midrectum and have discarded the Mikulicz-Paul operation except to terminate quickly an operation with gross contamination.

APPENDICITIS

Acute appendicitis rarely complicates an operation for carcinoma of the large bowel. If left without removal, serious complications may follow such as nearly cost the life of one of our younger patients. Evidence of a subacute or chronic appendicitis now leads us to do a simple appendicostomy, the appendix and mesoappendix being pulled through a small stab wound at McBurney's point.

REMOVAL OF GALLSTONES

Gallstones usually are removed to prevent a cholecystic attack during convalescence. Guided by the hand within the abdomen, a visceral forceps is passed through a short transverse incision, the apex of the gallbladder is exteriorized and aspirated, and the stones are removed by curet, forceps or "milking" and a drainage tube tied into the gallbladder. In an obese patient with a small gallbladder, the skin and fat may be more widely divided to the external oblique, beyond which it may not be possible to exteriorize and anchor the organ. There has been no complication from 7 or 8 of these added operations.

PERMANENT OR PALLIATIVE COLOSTOMY

Fourteen years ago one of us reached the conclusion that a permanent colostomy was not essential in the operative treatment of cancer of the intestine. In 480 consecutive operations for cancer of the large bowel performed since that time a permanent colostomy has not been used. In 3 patients, however, or less than 1 per cent, operative complications have left the patient with a colostomy which, because of evidence of cancer developing in the pelvis, was not closed.

For years palliative operation for ineradicable carcinoma of the large bowel has been a term synonymous with colostomy. Except in the presence of intestinal obstruction, to call colostomy a palliative or relief-giving procedure is an ironic misuse of terms. Colostomy brings gloom and disgust to the unfortunate patient with advanced carcinoma, and a new dependence on others. If the family cannot afford nursing aid, often it refuses to remove him from the hospital until, a constant burden, his demise gives relief to all concerned. As a result, our highest operative mortality for intestinal cancer has followed palliative colostomy. At present our preferred palliative operation is resection of the cancerous segment and end to end anastomosis. This eliminates the loss of blood, the diarrhea or obstruction, the suppuration and septic necrosis of the primary tumor. Even with residual large multiple growths in both lobes of the liver the patient may then show appreciable improvement in appearance, spirits and strength. Such a patient, who had lost 75 pounds (34 Kg.) in weight and had been bedfast for several months, became ambulant in eight days and returned home 300 miles away fifteen days after resection and end to end anastomosis. If the metastatic growths in the liver are small the patient may live

in apparently good health for from two to four years. One considered herself in good health for seven years after the radical resection. Even patients classed as inoperable and treated by a palliative colostomy occasionally may be restored to a period of comfort by elimination of both colostomy and tumor. A physician with metastasis in pelvis and liver, incapacitated for the six months following colostomy, rapidly improved and was able to resume practice for seven months after an end to end resection with removal of the colostomy. Another patient was incapacitated by a very troublesome intestinal prolapse eleven years after a Miles operation. The colostomy was moved from the abdominal wall to the perineum and, although small, slowly growing masses of colloid carcinoma were found in the pelvic floor, the patient became free from fecal leakage. During the seven years which have since elapsed the man has continued to be active; the local growth has again been partly resected but continues to grow slowly, with relatively little inconvenience.

Complications of a perineal colostomy are due largely to sloughing of the terminal bowel and the formation of a stenotic cicatricial opening, which may give the patient much distress. If the anal canal has been removed, every effort should be made to maintain a large perineal opening. With any suggestion of contraction the patient should be supplied with dilators (as a set of test tubes) to be used twice daily until an opening of adequate size is established, after which the dilators should be used every week or month, or whenever there is a tendency to contraction. As with an abdominal colostomy, 85 per cent of the patients need to empty the colon completely by irrigation or by quickly acting saline cathartic every second or third day.

SUMMARY

The adoption of radical excision instead of colostomy for patients with advanced secondary lesions from cancer of the large bowel has increased our rate of operability to over 96 per cent and also our mortality from resection but is considered well worth while. In the last 250 cases 16 (6.3 per cent) were considered inoperable. In the last 150 cases 5 were considered inoperable; 96.7 per cent had radical operations. Sixteen (10.6 per cent) died in the hospital. Deducting 11 with far advanced or ineradicable disease, the mortality was 3.6 per cent. Of the last consecutive 45 patients all had succinylsulfathiazole; 44 had radical resections with 1 death (2.2 per cent), a patient with advanced carcinoma of the liver who had an abdominal end to end anastomosis 5 cm. above the sphincters.

There were 24 end to end aseptic resections over a single clamp, 13 abdominoperineal resections with retention of a functional anus, 3 perineal resections for cancer of the anus and 3 eliminations of a colostomy left by other surgeons. No Mikulicz operation or colostomy was performed. Our tendency therefore is toward a wider use of end to end resection, the preservation of the uninvolved anus and the elimination of the Mikulicz operation except when serious peritoneal contamination renders a rapid termination of the intra-abdominal procedure desirable. In the past 480 operations there were 78 Mikulicz resections with 14 deaths, or a mortality of 17.9 per cent largely the result of serious complications.

CUTANEOUS MANIFESTATIONS OF THE FUNGI CAUSING DERMATOPHYTOSIS AND ONYCHOMYCOSIS

AND THEIR TREATMENT

ROYAL M. MONTGOMERY, M.D.
AND
ESTHER A. CASPER, B.S.
NEW YORK

With the demobilization of men and women following World War II, one can expect an increase in the incidence of dermatophytosis, or "athlete's foot," as this common ringworm infection of the feet is popularly known. Between 1940 and 1943 the Navy hospitalized 14,068 patients for fungous infections of the skin,[1] the large majority of them involving the groin and the feet. These patients lost 251,418 days from active service, representing 17.1 per cent of sick days lost for all skin diseases. The incidence of infection not requiring hospitalization is much higher. Since, even in normal times, from 50 to 90 per cent of the young adult population are affected at some period, it is important for the physician in general practice to be able to recognize the cutaneous manifestations of this common fungous infection. Early recognition of the causative fungus and proper therapy will aid materially in shortening the duration of the disease.

Though a ringworm infection of the palm was first observed in 1870 by Tilbury Fox[2] and later, in 1888, Pellizzari[3] reported 7 cases on the palms and soles, it was not until 1892 that a careful and systematic study of 25 cases was made by Djelaleddin-Moukhtar.[4] He was the first to make cultures from scales and vesicular fluid from the hands and feet. Later reports were made in 1908 by Whitfield[5] and in 1910 by Sabouraud.[6] The first in the United States to report cases of dermatophytosis were Montgomery and Culver, Hartzell and Lane. Ormsby and Mitchell[7] in 1916 were the first to make a comprehensive report on the disease. Their paper, which is still one of the best on the subject, covered 65 cases.

Whitfield[8] classified the disease according to its clinical manifestations into three main types, which were the acute vesiculobullous, the chronic intertriginous of the toes and the chronic hyperkeratotic of the palms and soles. The causative organism was generally not known. Ormsby and Mitchell, in their early report, recognized the fact that the invading organism probably was related to the subsequent clinical developments.

It is our purpose in this paper to correlate the cutaneous manifestations of ringworm of the feet and nails with the invading fungi.

From the New York Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University.

Read before the Section on Miscellaneous Topics, Sessions for the General Practitioner, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

At the New York Skin and Cancer Unit tabulation was made of the causative organisms in cases of dermatophytosis between 1935 and 1943 (table 1). Positive cultures from the feet showed that 65.4 per cent were caused by Trichophyton gypseum, 15.7 per cent by Trichophyton purpureum, 13.5 per cent by Monilia albicans and 2.8 by Epidermophyton inguinale. These account for 97.4 per cent of the cases. The remainder were due to unidentified organisms of the trichophyton type or other fungi. Thus four fungi cause practically all the cases of dermatophytosis found in New York and probably throughout the United States. However, the incidence of infection with these fungi varies in different localities; for instance, E. inguinale is more prevalent in France and England.[9]

In a majority of the infections by a particular organism, certain features predominate so it is possible in most cases to predict the invading fungus without culturing. This is also true of ringworm of the nail, which will be discussed later.

Laboratory examination, both microscopic and cultural, should be carried out to verify the diagnosis.[10]

TRICHOPHYTON GYPSEUM

Trichophyton gypseum, which is responsible for the largest number of infections, causes an acute inflammatory type of dermatophytosis in which vesiculation is the main feature. It may be preceded by slight scaling, maceration or fissuring between the toes for months or even years. In the macerated areas, minute vesicles are present. The infection of the interdigital webs may be irritated or aggravated by local medication, by friction from a shoe, by scratching or by heat, resulting in an acute vesicular or bullous eruption. The vesicles are usually limited to the sole or to the sides of the foot or the bulbs of the toes. More rarely they occur on the dorsum of the foot. The vesicles at first are deeply seated and contain a viscid fluid with very little erythema surrounding them. Later they may become pustular. In the early stage the vesicles appear singly and soon are found in groups. At times, groups of the vesicles coalesce to form extensive patches. The vesicular areas spread at the margin, dry up, scale and clear centrally. An overhanging serpiginous border may remain. Vesicles may reappear in a centrally healed area.

As the vesiclular fluid is absorbed, the vesicles become brown macules and later desquamate. The domes of the vesicles and the scales contain many elements of the fungi and thus are infectious. These vesicles may be secondarily infected with staphylococci or streptococci, causing an acute pustular eruption of the feet, cellulitis or lymphangitis. Even erysipelas or septicemia may result in the rare case.

Fig. 2.—Trichophyton purpureum infection, showing fine branny scales.

The presence of hyperhidrosis is frequently found with this type of dermatophytosis. The sweat produced, especially between the toes, where it is of a higher p_H, acts as a good culture medium for fungi and thus aids in the spread of the disease. Itching may be pronounced. Walking is frequently difficult in extensive cases.

TRICHOPHYTON PURPUREUM

In the noninflammatory type of dermatophytosis Trichophyton purpureum is the usual causative fungus.[11] The plantar surface is the common site of infection, although it may involve the side or dorsa of the feet, toes and toe nails. Any part of the hands may also

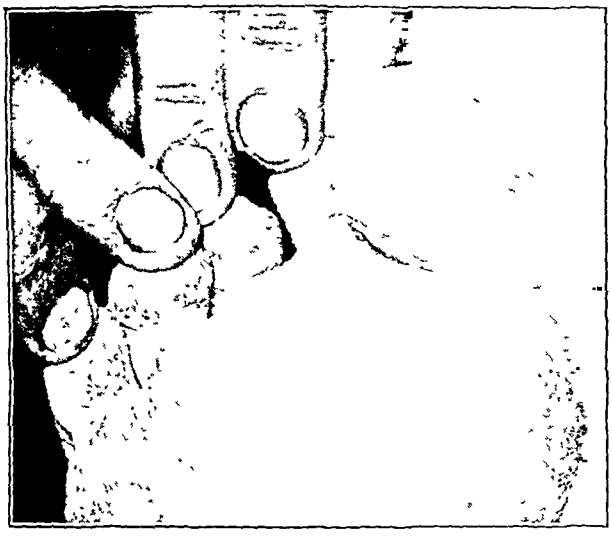

Fig 3.—Monilia albicans invasion, with maceration in all interdigital webs.

be involved. The entire sole or any part may be the site of infection. When extensive, the infected area spreads up the sides of the foot and heel. This makes a sharply marginated erythematous border, giving a "moccasin" effect to the foot. The infected skin is dull red and slightly thickened. The scaling, which is constant, is usually fine and branny. The absence of visible vesiculation in the presence of itching is a persistent feature. The infected sole is drier than usual. Irregular erythematous scaly patches may be found on the dorsa of the feet and toes. The degree of erythema may vary within a single patch, giving a mottled appearance. There is no tendency to central clearing.

The infection on the under surface of the toes is clinically similar to the plantar infection. Moisture will cause a small degree of maceration in the interdigital areas. If the entire toe is involved, the skin is thickened and dry with fissuring about the dorsal side of the joints. This noninflammatory type of dermatophytosis is more apt to be bilateral and symmetrical than the acute type caused by T. gypseum.

MONILIA (CANDIDA) ALBICANS

Infection of the foot with Monilia albicans, mycologically speaking, is not dermatophytosis because the organism is not a dermatophyte but a "yeastlike" organism. "Moniliasis" is the term used for infections by this organism.[12] It is a common cause of intertriginous infections. This organism is the cause of thrush, pruritus ani, perlèche and intertriginous infections of fingers, toes and other locations. It is included in this paper because it does cause a type of "athlete's foot" which is rather acute and difficult to cure. Diabetes may be a complicating factor in this infection.

When the feet are infected, the characteristic manifestation usually limits itself to the interdigital webs. The skin between the toes is bright red, weeping and fissured at the base. Exfoliated and macerated skin is present at the borders of these denuded or red areas and overhangs it. This infection usually involves both feet, and all interdigital webs. Occasionally it extends on to the dorsum of the foot, where the skin may be red and glazed or acutely inflamed. Occasionally vesicles are present on the plantar surfaces, from which this organism may be cultured.

EPIDERMOPHYTON INGUINALE

Epidermophyton inguinale, a cause of ringworm of the groin, also invades the feet. Sabouraud's first report [6] of E. inguinale infection of the feet includes an excellent clinical description. · Eight out of 10 cases of intertrigo of the toes he found [8] were caused by E. inguinale. The original site of infection is the base of the interdigital webs, but it ultimately reaches the folds of the flexor surface of the toes. Maceration and severe scaling are characteristic of the infection in the interdigital webs. As the infection spreads on the sole the skin is decidedly scaly with the scales larger and flakier than those found in a T. purpureum infection. Vesiculation may be present, but usually it is not very acute. The vesicles are rather dry and are interspersed in the scaling. As they mature they become small brown macules, which can be easily lifted off. The sole, in some cases, is erythematous. The usual infection limits itself to the toe area, though the entire sole may be involved. Often a concomitant infection of the groin with the same organism occurs.

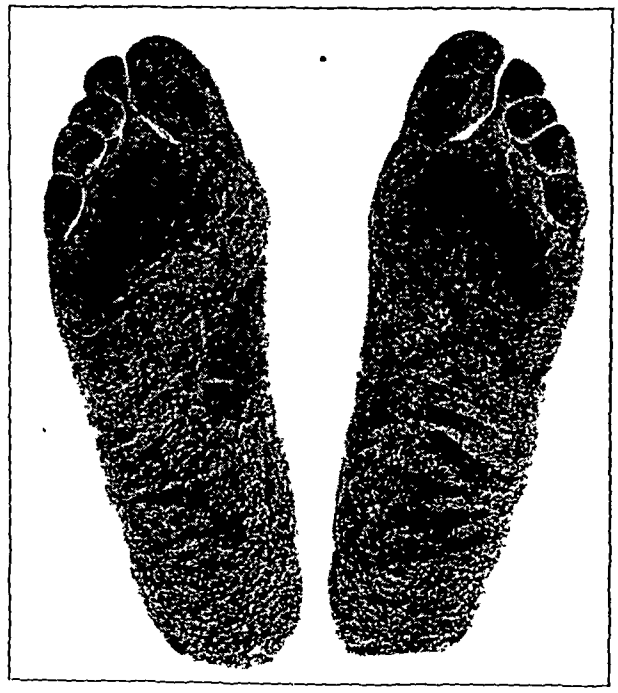

Fig 4.—Epidermophyton inguinale infection, with scattered vesicles and flaky scaling.

Hand infections may be caused by the same four fungi (table 1). The most frequent causative agent is M. albicans. This organism has been isolated in 55.1 per cent of our cases from the hands. The infection is usually limited to the interdigital webs, where it is known as "erosio interdigitalis blastomycetica." The infection is similar in appearance to that occurring between the toes.

12. Hopkins, J. G.: Moniliasis and Monilids, Arch. Dermat. & Syph. 25: 599 (April) 1932.

The other organisms also give a similar clinical appearance on the hands as on the feet. As this paper deals with infections of the feet only, hand infections will not be discussed. A detailed report on fungous infections of the hands has been made by Epstein.[13]

Dermatophytid [14] is an allergic response of the skin to fungi or their toxins. It manifests itself by vesicles

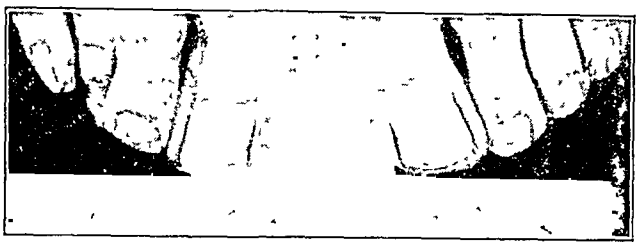

Fig. 5.—Leukonychia trichophytica, showing superficial white patches on many nails caused by Trichophyton gypseum.

on the palm and fingers and is usually more pronounced in cases of an acute fungous infection of the feet. For further information there are many excellent articles.[10]

NAILS

Favus of the nails, a type of ringworm, was first described in 1829 by Mahon,[3] which was ten years before Schoenlein described the causative fungus, Achorion. Baum and Meissner in 1853 described molds in the nails.[15] Others mentioned these lesions before the original reports by Fox, Pellizzari and Djelaleddin-Moukhtar on hand and foot infections. Whitfield's first case [5] of onychomycosis of the toe nails was caused by E. inguinale. This is of interest, because this fungus has not been isolated from the nails in any of the cases at the New York Skin and Cancer Unit.

The clinical manifestations of onychomycosis are more constantly similar for the individual organism than for their manifestations on the skin of the feet. The fungi most commonly seen in onychomycosis are Trichophyton gypseum, Trichophyton purpureum and Monilia albicans. Table 2 shows the incidence of causative fungi found in toe nail and finger nail infections at the New York Skin and Cancer Unit.

In the toe nail infections, T. gypseum was found in 63.5 per cent of the cases which were culturally positive, T. purpureum in 25.3 per cent and M. albicans in 5.6 per cent. The remaining 5.6 per cent were caused by unidentified trichophytons, T. niveum and 1 case by Achorion schoenleini (favus).[16]

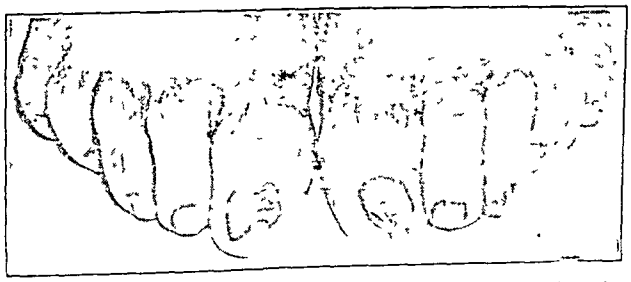

Fig. 6.—Trichophyton purpureum infection, showing big toe nails undermined and broken off.

In the most common type, that caused by T. gypseum, the infection is usually superficial. Superficial scaling is present. It often starts under the overhanging cuticle. It rarely invades the entire nail plate. There is one type of nail infection with this organism which is very typical, leukonychia trichophytica.[17] In this type small chalky white areas are present on the surface or in the substance of the nail plate. They may be single or multiple and may be irregularly shaped. They may or may not advance toward the distal end of the nail as it grows. This depends on their depth in the nail plate. The ease with which it can be shaved off shows its superficial nature. In long standing cases the infection may penetrate the entire nail plate. However, this is the exception. There is no paronychial inflammation present.

In nails infected with T. purpureum [11] the infection is deeper. The onset and progress are slow and insidious. There is little or no reaction in the subungual and paronychial tissues. The infection usually begins under the free border or along the lateral margins of the nail. Yellowish streaks appear under the nail plate from these locations. They gradually enlarge and the entire nail plate may be involved. The nail plate is loosely attached to the bed above the yellow discolored areas. The nail becomes brittle, dystrophic and loosened from the nail bed. It frequently becomes broken off and it is common to see a nail which is only one half present, the remaining portion of the nail being undermined and appearing both black and yellow from the débris and fungi accumulated there. This appearance is typical of both finger nails and toe nails. Concomitant infection of the toes or sole is usually present.

In nails infected with Monilia (candida) albicans the infection usually starts in the lateral nail groove, causing a slightly red paronychial swelling. Thin pus may be discharged from beneath the nail fold. The nail on its lateral border becomes dystrophic, and transverse ridges appear. The nail becomes dark because of débris accumulated under the loosened border. Later the entire nail may become involved. The nail plate in this infection does not become friable, yellow or white, as in Trichophyton infections. It is usually hard and as glossy as a normal nail plate. In toe nail involvement there is usually an infection of the toes. Finger nail infections with Monilia albicans are more common than toe nail infections. However, clinically they are similar Finger nail infection is common in housewives, dish-

washers, bakers and persons with similar occupations. Diabetes may also be a complicating factor.

Associated paronychia is a characteristic feature of this, and only of this, mycotic nail infection.

TREATMENT

There are many effective methods of treating dermatophytosis.[18] Intelligent therapy depends on the proper use of drugs in relation to the clinical appearance and identity of the causative organism. Most of the old drugs are still most effective. Variations in the treatment are mainly in cases in which T. purpureum and M. albicans are found or suspected to be the causative fungi.

In T. purpureum infections stronger fungicidal remedies are indicated. Double strength ointment of benzoic and salicylic acid (Whitfield's ointment), consisting of 12 per cent salicylic acid and 24 per cent benzoic acid in petrolatum, tincture of iodine 2 per cent and chrysarobin 3 per cent in petrolatum are all good fungicides and very helpful in these cases. Some cases fail to respond to these medications but respond with the use of stronger applications. Roentgen therapy does not give favorable results in this type of infection.

In M. albicans infection certain drugs are more efficacious than others. For local applications 3 per cent aqueous solution of gentian violet or brilliant green, 5 per cent aqueous solution of silver nitrate and

TABLE 3.—*Mild Fungicidal Ointment*

		Gm. or Cc.
℞	Salicylic acid	1
	Ointment of zinc oxide	15
	Ointment of ammoniated mercury (10%), q. s. ad	30

ammoniated mercury ointment 5 per cent are the drugs of choice. Silver nitrate can also be used in wet dressings in acute cases in 1:5,000 or 1:10,000 dilutions. The aniline dyes or silver nitrate solution tend to dry down the intertriginous eruptions due to M. albicans faster than other drugs. If diabetes is a concomitant condition it must be brought under control.

In cases caused by T. gypseum or E. inguinale the treatment must be varied according to the clinical manifestations.

If there is an acute inflammatory reaction, regardless of cause, soothing remedies should be used. The vesicles or bullae should be drained and wet dressings applied. There are a variety of solutions that may be used. All should be used warm. One may choose from saturated solution of boric acid, Burow's solution 1:20, potassium permanganate 1:2,000 or 1:4,000 and silver nitrate 1:5,000 or 1:10,000. If the infection is very pustular the latter gives the best results. If elevation of the foot is necessary, wet applications are applied; otherwise a foot bath is used.

When using wet dressings intermittently, paste of zinc oxide with 1 or 2 per cent phenol may be used between soakings. In the acute case 1 to 2 per cent aqueous gentian violet or brilliant green may be applied locally.

Indiscriminate use of proprietary remedies may precipitate an acute dermatitis. Many contain a high percentage of salicylic acid, some are alkaline in reaction and others contain a complex organic compound which has a high sensitizing index. The newly popularized phenol-camphor solution has caused many ulcerations. Generally speaking, it is safer to use standard drugs such as those in the National Formulary or the United States Pharmacopeia.

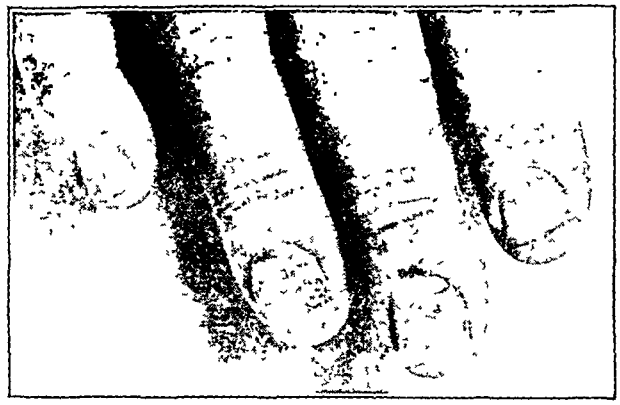

Fig. 7.—Monilia albicans infection, with paronychia and dystrophy of the sides of the nail plate.

As the acute phase subsides, fungicidal remedies may be used. They should not be used in the acute case. This is one of the common mistakes made in the treatment of dermatophytosis. Mild fungicides, such as

Fig. 8.—Severe burn from the application of 50 per cent phenol and camphor solution for "athlete's foot."

gentian violet, brilliant green or one-third strength Whitfield's ointment, may be used twice daily on the affected areas. The ointment given in table 3 is frequently of value as a mild fungicide to tide a case over between the acute and more chronic lesions.

Later stronger fungicidal remedies are indicated. Whitfield's ointment one-half to full strength is helpful. Tincture of iodine 0.5 to 1 per cent may be used. One to three per cent chrysarobin ointment is also helpful.

Symposium on the Practical Management of Eczematous Ringworm of the Hands and Feet (Athlete's [illegible] and Dermatophytids), J. Invest. Dermat. 3: [illegible], M. R. Fungous Infections of the Foot, J. A. M. A. 124: 751 (March 18) 1944.

After the case is clinically cured it is advisable to use a mild fungicide such as one-third strength Whitfield's ointment or the powder mentioned in table 4 a few times a week to prevent recurrences. Sterilization of shoes by means of solution of formaldehyde (U. S. P. XII) and boiling the socks are important.

Prophylactic treatment following a day at the beach or a swim in a pool is advisable. This should be any mild fungicide such as the fungicidal powder.

TREATMENT OF NAILS

It is most important to cure ringworm of the toe nails, for it is a focus of reinfection.

In the treatment of nails there is a wide variety of opinion as to the most efficacious method to be used. Some advise surgical evulsion of the nail. This is a rather radical procedure. The more conservative methods of treatment will accomplish the same result with less pain and discomfort.

It is important in all types of nail infections to remove mechanically as much of the infected portion of the nail as possible. With this procedure the medications applied will be more effective.

In the superficial nail infections the scaly surface of the nail should be shaved off with a scalpel. The white chalky areas may be removed in a similar manner; however, shaving has to be a little deeper. The shaving

TABLE 4.—*Fungicidal Powder*

℞	Salicylic acid	2.4
	Tannic acid	8
	Boric acid	36
	Purified talc, q. s.	ad 120

is continued until normal nail plate remains. With this completed, mild tincture of iodine is applied daily to the nail. Other strong fungicides may be applied, but this method is a simple one.

In the deeper nail infections caused by T. purpureum, treatment is more difficult and more tedious. The removal of the infected portions of the nails must be painstaking. For this work a pair of clippers, a scalpel and a small nail chisel are needed. As much of the infected nail as possible must be removed, especially the lateral portion, which may lie deep in the nail groove. Forty per cent salicylic acid plaster is applied to the exposed nail bed and the adjacent nail. A 60 per cent salicylic acid in white ointment (U. S. P. XII) may be spread on the medicated side of the 40 per cent plaster to reinforce its strength, thus making it more keratolytic. The medicated plaster is held in place by adhesive. These applications are changed once weekly following the complete removal of macerated tissue and undermined nail. This procedure is carried out until the nail plate is firmly attached to the nail bed. This will take from four to six weeks. Following this, strong fungicides are applied to the nail. Mild tincture of iodine, 20 per cent silver nitrate solution or 3 per cent chrysarobin ointment may be used. This procedure must be done at each visit to insure a normal nail. With T. purpureum infection, treatment has to continue from four to six months and sometimes longer. However, the interval between treatments can be spaced from two to four weeks after discontinuing the salicylic acid treatment. Roentgen therapy for this type of nail infection has been disappointing.

In Monilia albicans infection of the nails the treatment must be varied. First, mechanical removal of as much of the infected and undermined nail as possible is important. Roentgen rays help in reducing the paronychial swelling. The application in the office of a 10 to 20 per cent silver nitrate solution aids. For daily home applications 3 per cent alcoholic solution of gentian violet or brilliant green or a 5 per cent ammoniated mercury ointment is helpful. In addition, daily scraping with a glass slide of the lateral portions of the nail will aid in removing the infected nail plate. In cases in which pain is present and pus exuding, wet dressings of warm saturated boric acid solution are helpful.

Treatment of concomitant infections of the toes and sole is most important in all cases of ringworm of the toe nails.

SUMMARY

Dermatophytosis is a prevalent mycotic infection. In New York the majority of the cases are caused by Trichophyton gypseum, with Trichophyton purpureum, Monilia albicans and Epidermophyton inguinale causing the rest

Trichophyton gypseum causes an acute inflammatory type of dermatophytosis in which vesiculation is the main feature. Its infection of the nail plate is usually superficial and is manifested by scaling or small irregular white areas.

Trichophyton purpureum produces a noninflammatory dermatophytosis characterized by fine branny scaling and an absence of vesiculation. In nail infections this fungus invades the under portion of the nail, causing yellow undermined areas. The nail plate may be broken off or destroyed.

Monilia albicans infections of the feet are characterized by red and macerated areas usually involving all the interdigital webs. Nails show a paronychial swelling, with the lateral borders of the nail plate ridged and undermined.

Epidermophyton inguinale infection of the feet shows maceration and severe scaling on the toe webs and flaky scales on the sole. Nail infections have not been observed by us.

The basic principle of treatment in dermatophytosis of the feet is the use of soothing wet dressings or pastes in the vesicular stage and of fungicidal remedies after the acute phase has subsided. In the case of infections with Trichophyton purpureum, strong fungicides must be used. In invasions with Monilia albicans, mercurials, silver nitrate or gentian violet is preferred. In onychomychosis it is important to remove all infected nail tissue mechanically before applying fungicides.

CONCLUSIONS

In the majority of cases the invading fungus causes characteristic cutaneous manifestations by which it can be suspected.

Dermatophytosis and onychomycosis should be classified according to the etiologic agent rather than by clinical manifestations.

Early recognition of the invading fungus and intelligent treatment shorten the duration of the disease.

ABSTRACT OF DISCUSSION

DR. JOHN H. LAMB, Oklahoma City: With the great numbers of American soldiers living in tropical climates with their intense humidity, the treatment of fungous disorders of the feet has been a major problem. The authors have stressed the value of knowing the type of fungus which one is treating. Many physicians have adopted the routine use of the various dye products, gentian violet and brilliant green for all types of dermatophytosis. This is satisfactory in Monilia albicans infection but it will not be curative in the more recalcitrant Trichophyton purpureum. There is no stock prescription for dermatophytosis. All medications revolve on the phases of the infection, whether acute, subacute or chronic, and on the variations of the skin reactions to the fungous toxin. The portion of the paper on nail infections was most correct and practical. In these days of working too fast we find it impossible to take the time necessary for curetting and shaving off the nail from the nail bed. I have been using a very cheap and extremely useful motor driven burr, which in a few minutes will remove almost all of the diseased nail. Locally in some stubborn cases I have found a paste to be efficacious which is composed of chrysarobin powder mixed in a base of pure saponated solution of cresol which has been saturated with salicylic acid. This is applied to the nail bed once every two weeks. The skin and periungual areas are protected by a bland salve.

DR. ARTHUR C. CURTIS, Ann Arbor, Mich.: Dr. Montgomery has described the four fungous infections that comprise almost 98 per cent of the causes of tinea pedis in New York City. In all probability that percentage holds for the University Hospital in Ann Arbor. To one who is not entirely familiar with mycologic terminology and mycologic characteristics the names of these fungi will soon be forgotten. Would it not be better to remember these fungi by the type of reaction that they produce rather than by their generic names and to divide the fungous infections into the acute or inflammatory types, the subacute types and the chronic types? Too often, after the diagnosis of tinea pedis is made, the desire to destroy the fungus takes precedence over the treatment of the reaction that the fungus has produced. The result is that many of these patients will develop a severe dermatitis venenata. Severe types of dermatophytosis frequently are secondarily infected and cellulitis, lymphangitis or erysipelas may be a complicating factor. Again, in many of these cases the etiologic fungus must be forgotten until the secondary infection is controlled. Monilia infections can be of minor importance or they can be very serious; some cases may be fatal. The treatment outlined for monilial infections by Dr. Montgomery is most efficacious. On the other hand, one should not forget that, experimentally and also clinically, monilia infections have been associated with definite riboflavin deficiencies, and in some of these cases that do not respond to satisfactory treatment one should also introduce into the therapy vitamin B complex or riboflavin. Chronic tinea infections of the feet are best illustrated by Trichophyton purpureum and, in my hands, at least, have been extremely refractory to treatment, even with such a remedy as double strength Whitfield's ointment. I should like to ask Dr. Montgomery whether or not, in many of his cases, he actually cures these cases or just arrests the disease temporarily and then at a later date has the patient back on his hands again.

DR. ROYAL M. MONTGOMERY, New York: In answer to Dr. Curtis's question about Trichophyton purpureum infection, it is certainly difficult to cure. In the majority of extensive cases I believe that they are arrested and not cured. Maybe Dr. Lamb can report in another fifteen years how his infection is progressing. As far as nail infections are concerned, it is most important to remove mechanically as much of the infected portion of the nail as possible. Dr. Lamb uses a burr, which is most effective; otherwise one can use a scalpel. But it is always important to remove the undermined portion of the nail and then apply a fungicidal remedy. The remark that Dr. Curtis made about Monilia albicans infection associated with riboflavin deficiency is interesting. We have seen patients with moniliasis at the New York Skin and Cancer Unit who also have a vitamin C deficiency. Probably there is hypovitaminosis in many of these infections.

ORAL ADMINISTRATION OF PENICILLIN

A PRELIMINARY REPORT

FREDERIC GERARD BURKE, M.D.
SIDNEY ROSS, M.D.
WASHINGTON, D. C.
AND
LIEUTENANT CLIFTON STRAUSS
M C S, U.S.N.R.

During the early clinical trials, Abraham, Florey and their associates,[1] investigating the various routes of administration of penicillin, tried the oral route and found that the substance was rapidly destroyed by the hydrochloric acid of the stomach. Their attempts to raise the p_H of the gastric contents by the use of sodium bicarbonate were not particularly successful. While they failed to obtain adequate concentrations in the blood after administering solutions of penicillin orally, they were able to recover satisfactory antibacterial amounts in the urine and by this means successfully treated a urinary tract infection in a 6 month old infant. They suggested the use of capsules, but after unsuccessful attempts with phenyl salicylate coated vehicles, abandoned this method. Rammelkamp and Keefer[2] corroborated the previous work of Florey and others[1] in demonstrating the inactivation of penicillin by hydrochloric acid. These investigators administered penicillin by the oral, duodenal and rectal routes. For these experiments they used a solution of 200 cc. of tap water containing 10,000 and 20,000 units of penicillin. Three subjects were given this solution by mouth after fasting for twelve hours. One of the subjects received 4 Gm. of sodium bicarbonate ten minutes prior to the ingestion of the penicillin solution. They concluded that the absorption following oral administration was poor, as demonstrated by the low concentrations in the blood. They also noted that absorption following intraduodenal administration was more efficient than the oral or rectal routes, the serum concentration levels approximating those obtained after intramuscular injection. Rectal administration was found to be unsatisfactory, probably on the basis of the inactivating influence of Escherichia coli.[3]

In 1943 Rammelkamp and Helm[4] reported the results of the oral administration of a penicillin solution containing 1,000 Oxford units per cubic centimeter, giving a total of 20,000 units to 2 patients who had achlorhydria associated with pernicious anemia. The curve of the blood concentrations was greater than that observed in normal subjects and was not unlike that obtained after intramuscular or intraduodenal adminis-

tration. They also noted that saliva, bile and succus entericus did not exhibit any inactivating influence on penicillin.

The necessity of frequent doses in the parenteral administration of penicillin is obligatory in order to maintain adequate antibacterial levels in the blood.[5] At the present time it is customary to administer penicillin parenterally at least every three hours in order to maintain therapeutic blood concentrations. Even with this regimen there frequently occurs a hiatus of from one-half to one hour between injections, during which time effective blood levels are not demonstrable. Continuous intravenous administration provides more constant concentration, but the incidence of thromboses is great enough to make the intramuscular route preferable.[6] Continuous intramuscular administration has been found to produce considerable discomfort. The disadvantages of such regimens to the patient and to the hospital personnel are manifest. Furthermore, hospitalization is mandatory for these methods of administration.

These inconveniences have stimulated investigation of a simplified method for prolongation of satisfactory blood levels. Romansky[7] has recently shown that single injections of penicillin combined with beeswax and peanut oil will produce and maintain efficient concentrations in the blood for six to ten hours. Chilling of the deltoid region before and after injection, thus producing vasoconstriction as a means of prolonging absorption of penicillin, has been recently recommended.[8] Diodrast[9] or para-amino hippuric acid[10] has been given simultaneously with penicillin, and it has been found that the serum concentrations reached greater heights with prolongation, probably the result of a depression of the excretion of penicillin from the kidneys.

The advantages of the oral route are self evident and require little elaboration. By this method a certain percentage of patients may be treated at home, thus obviating the necessity for hospitalizing every case as is the current practice when penicillin is indicated. Further, the administration of penicillin orally is considerably more convenient and precludes the need for frequent injections. In the past few months commercial production of penicillin has been so accelerated that its greater availability now permits more widespread application. A result of this increased production permits a reevaluation of the feasibility of oral administration.

The present report represents an attempt to ascertain whether or not therapeutic blood levels of penicillin could be obtained by this method of administration.

METHODS AND MATERIALS

It is clear that, to avoid inactivation, penicillin must be protected from the destructive action of hydrochloric acid in the stomach. In addition, penicillin must be absorbed from the small intestine before meeting the inhibitory influence of Escherichia coli. For the purposes of the experiments reported here it was decided to use capsules as a mechanical protection for the penicillin in its passage through the stomach after ingestion.

In preliminary experiments plain gelatin capsules were found to disintegrate promptly when immersed in gastric contents aspirated from normal subjects. Immersion in tap water and saline solution also resulted in the rapid loss of integrity. Because of this the powdered form of penicillin instead of solutions in water or saline solution was used. A method for protecting the integrity of the capsule was devised and consisted in a preliminary hardening by the use of solution of formaldehyde and alcohol immersion. Capsules treated in this manner were stable for one to two hours in aspirated gastric contents. This in vitro experiment does not take into consideration the probably mechanical pressure that is brought to bear on the capsule by peristalsis in the stomach; in vivo, this force could conceivably hasten disintegration. Additional protection was given the penicillin by the use of a double capsule. The contents of an ampule containing 100,000 units of powdered sodium penicillin were transferred to a gelatin capsule (No. 1), which was moistened and sealed and in turn placed in a second capsule of the next larger size (No. 0). It was then placed in solution of formaldehyde U. S. P. diluted 1:20 for five seconds, followed by immersion in 95 per cent alcohol for five minutes. One hundred thousand units of sodium penicillin in the powdered form was adequately accommodated in a No. 1 capsule. Physical transfer of the penicillin involved the loss of a small quantity of the substance; the exact amount was not known, but probably represented about 5,000 units.

In view of the inactivating influence of gastric acidity on penicillin, it was reasoned that neutralization of the hydrochloric acid would reduce this hazard. For this reason, aluminum hydroxide[11] was used, having been selected in preference to sodium bicarbonate, since the latter is known to have a rebound action in producing further stimulation of hydrochloric acid after initial neutralization. In our experiments two aluminum hydroxide tablets, which in preliminary tests were found to neutralize gastric contents within fifteen minutes after ingestion, were swallowed one-half hour prior to taking the penicillin capsules.

It was thought desirable to determine the relation of meals to the oral administration of penicillin, and toward this end four experiments were conducted before meals and six after meals.

The subjects selected were normal men weighing between 165 and 200 pounds (75-91 Kg.). Samples of venous blood were taken at the end of one-half hour, one hour and at hourly intervals thereafter and assayed for penicillin concentrations according to the method of Rammelkamp,[12] using B hemolytic streptococcus 203 as the indicator organism. In one experiment urine samples were similarly collected and assayed.

COMMENT

In our studies a characteristic common in all instances of penicillin given by mouth was the rapid absorption from the duodenum, as indicated by the initial rapid rise within the first half hour; the highest level obtained in all the curves occurred within one-half hour after the capsule was ingested.

In the two experiments when 200,000 units of penicillin was ingested (chart 1), initial levels at the end

of a half hour were 9.984 Florey units and 2.496 Florey units. In the instance of the higher level of these two curves, penicillin was taken two hours before dinner. In the second case the capsule was taken one-half hour after dinner. The subsequent levels taken at hourly intervals show a moderately rapid fall closely paralleling each other in these 2 cases. As will be noted, a therapeutic level was present after five and one-half hours in one instance and after four hours in the other.

A similar initial rapid rise during the first half hour was found in the 6 graphs representing the ingestion of 100,000 units of penicillin (charts 2 and 3). In one instance a level of 9.984 Florey units was achieved, in another 2.946 Florey units, in 2 cases 1.248 Florey units, another 0.624 Florey unit and in 1 case 0.156 Florey unit. Therapeutic levels of penicillin were assayable at the end of two hours in all cases. In 3 of these cases it was present in adequate concentrations at the end of three hours and in 1 case at the end of four hours. The appearance of sizable amounts of penicillin in the urine (chart 4) indicates rapid excretion from the kidneys after oral administration.

In two other experiments in which 100,000 units of penicillin was ingested there was no assayable level detected at the end of one hour. The reason for these

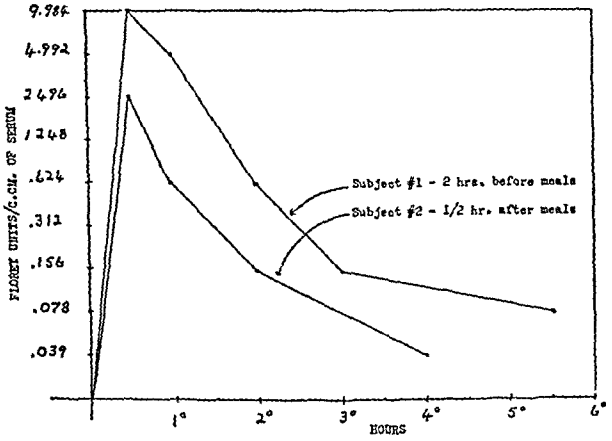

Chart 1.—Penicillin blood levels after oral administration of 200,000 units in a single dose.

two failures is not clear but may represent a premature inactivation of the penicillin in the stomach by hydrochloric acid. It should be noted that in both of these instances the penicillin was taken shortly after meals.

The relationship of meals to the absorption of penicillin must be evaluated, as the prolonged stay of the penicillin capsule in the stomach invites the inactivating influence of hydrochloric acid if the protective capsule is dissolved. As previously noted in a pilot experiment, the formaldehyde-alcohol prepared capsules retained their integrity only for one to two hours in the aspirated stomach contents. Therefore the necessity for the capsules to reach the duodenum within this hiatus is manifest. As already noted, six of our experiments were conducted after meals and the remaining four before meals. No categorical statement can be made on the basis of these experiments, but the impression is that slightly higher penicillin levels were obtained when the capsules were taken on an empty stomach. This is probably accountable on the basis of a more precipitous passage of the capsule into the small intestine from the stomach when the latter is empty. From these preliminary experiments it would seem advisable to administer penicillin orally at suitable intervals before meals. It is further suggested that a diet low in fat content, with high fluid intake, would guard against prolonged exposure to the inactivating influence of the gastric juice. The antacid used in these experiments, aluminum hydroxide, was employed empirically, and the importance of its role cannot be evaluated until further experimentation.

It is interesting to contrast the penicillin levels obtained after oral administration with the levels

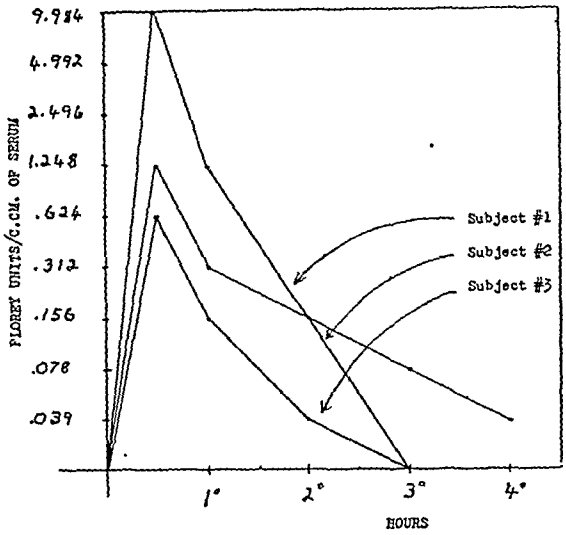

Chart 2.—Penicillin blood levels after oral administration of 100,000 units (one hour before meals) in a single dose.

reported after parenteral injection. The rapid appearance of large amounts of penicillin within the first half hour is common to all three modes of administration (chart 5). After intravenous administration of 40,000 units of penicillin, Rammelkamp [2] noted a very rapid rise in the blood level, the highest point being achieved within the first ten to fifteen minutes, followed shortly thereafter by a rather precipitous fall during the first hour, with only a trace of penicillin detectable after two hours. When 45,000 units was injected intramuscularly [7] the highest level was usually attained in

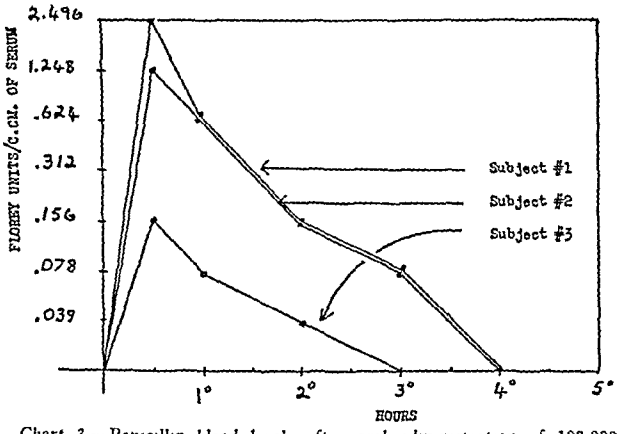

Chart 3.—Penicillin blood levels after oral administration of 100,000 units in a single dose (after meals).

about one-half hour, the rise, as one would expect, being less striking than when given intravenously, and then proceeded to drop more slowly, with detectable levels present at two to three hours. In the present experiments, when 100,000 units was given orally it was somewhat surprising to note the high initial levels after a half hour, indicating a rapid passage of the capsule into the small bowel. Reference to chart 5 shows the

average curve obtained after the ingestion of this amount. The highest level was achieved in about one-half hour, followed by a moderately rapid fall, with assayable levels still present after three or four hours. It is probably fair to conclude that levels obtained when employing the oral route exceeded both in concentration and in prolongation those levels

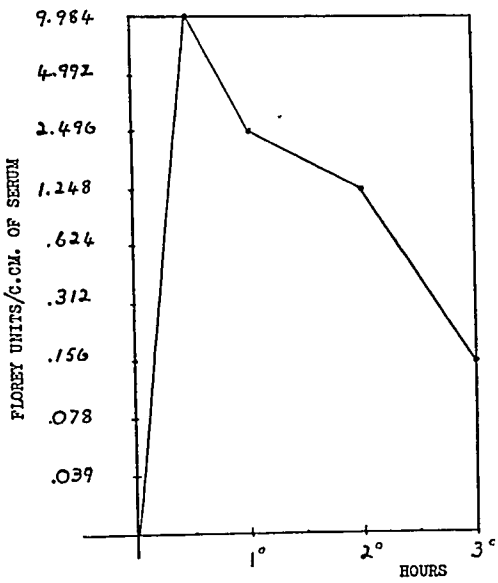

Chart 4.—Penicillin levels in the urine after oral administration of 100,000 units in a single dose.

obtained by parenteral administration when approximately twice as much penicillin is given. It would not seem unreasonable to expect that if comparable doses of penicillin had been used in these experiments the levels would rival those obtained after parenteral administration. Amounts of 100,000 and 200,000 units were used in these experiments rather than smaller doses which might well have been similarly efficacious. It should be noted that no objective or subjective toxic symptoms were produced when these large amounts were ingested. Division of the powdered material into smaller quantities was not feasible in our laboratory because of the physical error associated with the transfer of smaller amounts, due principally to the hygroscopic character of the sodium salt. However, experiments should be performed to test the efficiency of smaller doses with 25,000 and 50,000 unit capsules.

In view of the greater availability of penicillin today, with the consequent reduction in cost, it would not be an important deterrant if somewhat larger amounts of penicillin are required when the oral route is used. This is especially true when one takes cognizance of the incontestable advantages and convenience afforded by the oral route of administration.

When 200,000 units of penicillin was employed (chart 1) it will be noted that the levels were higher, with therapeutic concentration being maintained for one to two hours longer than when 100,000 units was taken, suggesting that the concentration and prolongation of penicillin the blood is more or less directly proportional to the oral dose employed.

The oral administration of 100,000 units of penicillin every three hours in the manner outlined would insure adequate levels in the blood for most susceptible infections. Rammelkamp and Keefer [13] found that the degree of antibacterial action was directly related to the concentration of penicillin in the serum and found the maximum effects against Streptococcus hemolyticus to be in concentrations of from 0.019 to 0.156 Florey unit per cubic centimeter of serum. Against Staphylococcus aureus, slightly higher levels were necessary, at least 0.156 Florey unit being required for a maximum effect

The feature of a rapid appearance of large amounts of penicillin in the circulating blood was common to oral and parenteral methods of administration. While no harmful effects from relatively high levels have been reported, it is questionable whether concentrations above 0.312 Florey unit per cubic centimeter have any added antibacterial value. It would be distinctly advantageous to secure an absorption curve that would guarantee therapeutic amounts in the serum over a longer period of time. One method of obtaining prolongation would be to administer larger doses by mouth, as evidenced by chart 1, when 200,000 was ingested; therapeutic levels were obtained in these cases for four to five and one-half hours. However, this dosage seems unpractical at the present time. A more plausible method would be one employing an inert vehicle that would slow down absorption from the small intestine and provide a plateau type of concentration curve with prolongation. Romansky has recently obtained therapeutic blood levels for six to ten hours by the intramuscular injection of 100,000 units of penicillin combined with 3 per cent beeswax in peanut oil.[7] We contemplate further experiments to determine whether prolongation can be achieved by the ingestion of penicillin in capsules using an inert vehicle as the solvent If this can be accomplished, obviously less frequent doses would be necessary. Furthermore, in cases when combined sulfonamide-penicillin therapy is indicated, both drugs could probably be given on a four to six hour dosage schedule.

The limitations of the administration of penicillin by the oral route are few. It would not be practical to employ this method for patients who have persistent vomiting or who are comatose. Also it is evident that

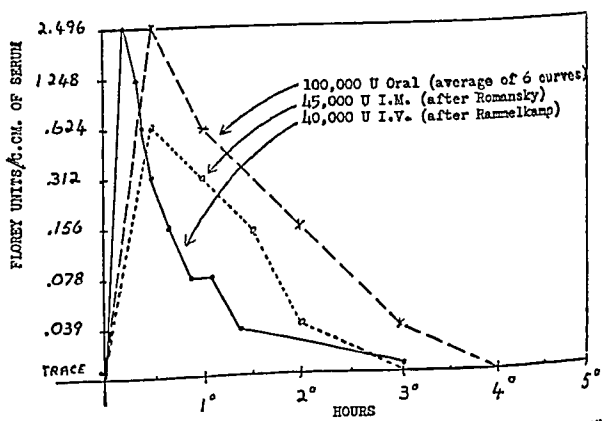

Chart 5.—Comparison of penicillin blood levels after oral and parenteral administration.

ingestion of penicillin capsules would not be satisfactory for infants and very young children, owing to their inability to swallow them with facility.

CONCLUSIONS

1. Adequate penicillin blood levels were obtained by oral administration when the drug was protected from the inactivating action of hydrochloric acid in the stomach.

13. Rammelkamp, C. H., and Keefer, C. S.: Penicillin: Its Antibacterial Effect in Whole Blood and Serum for the Hemolytic Streptococcus and Staphylococcus Aureus, J. Clin. Investigation 22: 649 (Sept.) 1943.

2. Penicillin concentrations determined after ingestion of 100,000 units compared favorably and in some respects surpassed those obtained after administration of 40,000 units parenterally. When 200,000 units was ingested, higher and longer sustained levels were observed, suggesting that prolongation and blood concentrations are directly proportional to the dosage employed.

3. No objective or subjective symptoms of toxicity were observed after single doses of 100,000 and 200,000 units of penicillin orally.

THE OVERWEIGHT OBSTETRIC PATIENT

LIEUTENANT (jg) LESTER D ODELL, U. S. NAVY
AND
WILLIAM F. MENGERT, M.D.
DALLAS, TEXAS

Because of a clinical impression that considerable numbers of obese women pass through the obstetric division of the Department of Obstetrics and Gynecology at the University of Iowa College of Medicine, it was decided to review the case histories of all women weighing 200 or more pounds (91 Kg.) at or before birth of a potentially viable baby (1,500 Gm. or more). No record was included in which the child weighed less than 1,500 Gm.

PATIENTS

Seven hundred and sixty records were found and included 641 obese women, of whom 542 were delivered once and 99 two to six times.

During the same period, Jan. 1, 1926 to Dec. 31, 1942 inclusive, 16,644 deliveries took place. The incidence of obese women was therefore 3.85 per cent, or 1:26 (641 obese women), and the incidence of deliveries among obese women was 4.57 per cent, or 1:22 (760 deliveries). These figures represent a greater incidence of obesity than that reported (1:30) by Matthews and Der Brucke.[1]

Fourteen sets of twins, an incidence of 1:54, occurred, making a total of 774 babies born to these obese women during the period of observation. This incidence of twinning is considerably above that generally reported. It may be that the weight of the second twin was sufficient to include a few women in the series when otherwise the antepartum weight would just have failed to reach 200 pounds.

The age, the weight at the time of delivery and the number of previous pregnancies are recorded in tables 1, 2 and 3. It will be seen that the average age at the time of delivery was less than 30 years, the average weight was 224 pounds (101 Kg.) and that only 16.9 per cent of these patients were primigravidas. In other words, these women tended to be relatively young and fertile, since the number of multigravidas was almost five times that of primigravidas.

From the Department of Obstetrics and Gynecology, State University of Iowa College of Medicine.
Read before the Section on Obstetrics and Gynecology at the Ninety Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.
This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

1. Matthews, H. B., and Der Brucke, M. G.: "Normal Expectancy" in the Extremely Obese Pregnant Woman, J. A. M. A. **110**: 554-559 (Feb. 19) 1938. Zollei, C. M.: Geburtsverlauf und Wochenbett bei übergewichtigen Frauen, Monatschr. f. Geburtsh. u. Gynak. **113**: 25-56, 1942.

ANTEPARTUM COMPLICATIONS

Antepartum complications are recorded in table 4. Toxemia of pregnancy was noted 239 times, or 31.4 per cent, a figure in agreement with previous observations. The next most frequent finding was glycosuria. Only 1 woman suffered from diabetes mellitus and another developed it later. Although glycosuria was recorded only when discovered on at least 2 occasions, the presence of sugar in the urine seemed to possess little clinical significance during the period of study. It is possible that glycosuria in these patients merely represented repeated overindulgent ingestion of carbohydrate. The association of hypertensive disease and glycosuria in 53 patients could probably be accounted for on the basis that relatively a large group of these women suffered from the former.

LABOR

Although attention has repeatedly been called to the excessive frequency of abnormal presentation in the obese woman, the experience of this series (table 5) does not confirm the observation. It will be noted that breech alone presents a slightly elevated incidence. Occiput posterior was diagnosed at the end of labor and therefore was not as frequently recorded as it might have been if noted at the onset. Perhaps the greatest difficulty caused by obesity with regard to presentation and position lies in the difficulty of diagnosis. With normal landmarks obscured by intervening layers of adipose tissue, it is difficult for the obstetrician to be certain of any palpatory findings.

There has been considerable discussion of the relation of obesity to length of labor. Eight and one-tenth per cent of the labors of this series lasted less than three and 95.0 per cent less than thirty hours. On the other hand, prolonged labor, thirty or more hours, occurred 38 times (5.0 per cent), a second stage of two or more hours 31 times (4.1 per cent) and a third stage, of thirty or more minutes, 32 times (4.2 per cent).

Postpartum hemorrhage, 600 cc. or more, was noted in 54 patients (7.1 per cent) and necessitated the Credé maneuver in 7 and manual removal of the placenta in 3 patients. Usually accepted incidences of postpartum hemorrhage vary between 5 and 6 per cent.

OPERATIONS

The operative incidence (table 6) is approximately twice the usual clinic incidence. This figure is not as high as others[1] previously reported. Two of the 8 versions and extractions were performed electively on the second twin. Almost half of the operations were low forceps necessitated by prolongation of the second stage of labor.

One of the more serious complications of labor occurred in G. H., aged 35, octigravida, septipara, weighing 240 pounds (109 Kg.). At the end of a prolonged labor an unsuccessful midforceps operation followed by version and extraction resulted in a complete uterine tear 7 cm. long but not involving the cervix. Her course following subtotal hysterectomy was febrile, but she was discharged on the nineteenth day. The child, which was hydrocephalic with a meningomyelocele, was stillborn and macerated.

THE CHILD

The average birth weight was 3,580 Gm. (table 7), confirming the general opinion that obese women tend to give birth to large babies. Approximately 57 per cent of the infants weighed more than 3,500 Gm. at

birth. Thirty-five of the infants died, a mortality rate of 4.5 per cent. This figure is only slightly more than infant mortality rates for 1942 for the country at large. Table 8 gives the cause and time of death. Twenty-six were stillborn and 9 died during the neonatal period. Of the 26 stillborn babies, 15 died before the onset and

TABLE 1.—*Age*

11 during the course of labor. A relatively high proportion of intrauterine death (43 per cent) is evident and probably related, at least in part, to the increased incidence of hypertensive disease. There is a strikingly low incidence of death from immaturity, another expression of the general tendency of these babies to be large at birth. Of the live born children 60.8 per cent were wholly and 25.1 partially breast fed, while 14.1 per cent were artificially fed.

PUERPERIUM

Puerperal complications, chiefly sepsis, occurred in 96 women, a morbidity incidence of 12.6 per cent. Nonfatal embolus and thrombophlebitis each occurred in 1 patient.

There were 4 maternal deaths, 0.53 per cent, a figure twice as great as the maternal mortality rate for 1942 for the country at large. However, it should be remembered that the time interval of the present series dates to Jan. 1, 1927 and that comparison with mortality rates of 1942 is not necessarily accurate. Brief histories of each of these fatalities follow:

1. L. G., a sextigravida, quadripara aged 40, was admitted Jan. 22, 1933 in labor at term with a temperature of 102 F.,

cough, hemoptysis and cyanosis. Death ensued twenty-seven hours after a brief labor and was thought to have been caused by influenzal pneumonia.

2. M. B., a tertigravida, secundipara aged 26, was delivered spontaneously on March 30, 1936 of a normal child. Immediately post partum a preexisting third degree tear was repaired. The patient developed sepsis and clinical signs of peritonitis and died on the seventh postpartum day.

3. E. G., a primigravida aged 27, developed sepsis after a normal, spontaneous labor. Autopsy on the fourteenth postpartum day revealed generalized peritonitis, acute endometritis, myometritis and bronchopneumonia. The causative organism was a hemolytic streptococcus.

4. R. H., a septigravida, sextipara aged 40, was admitted on July 16, 1938 at term with a normal blood pressure, 1 plus albuminuria and edema of the ankles. Twelve days later a routine medical induction with premature artificial rupture of the membranes was followed by a thirty-two hour period of latency during which the patient developed a fever of 104.6 F. She suffered acute circulatory collapse immediately after a twelve hour labor and developed anuria, from the effects of which she died on the thirteenth day. Since no autopsy was permitted, the cause of the anuria was not ascertained.

REPEATED PREGNANCY IN OBESE WOMEN

Ninety-nine of the obese women of the present series were delivered in the clinic two or more times. Eighty-five were delivered twice, 11 three times and 1 each four,

five and six times. In all, 218 deliveries resulting in 223 children (5 sets of twins) were observed among these 99 women. One of the mothers, previously mentioned, died of influenzal pneumonia following the second delivery at University Hospitals. Eleven (4.9 per cent) of the 223 infants succumbed.

Only 16 (16.2 per cent) of these 99 women went through successive pregnancies without a single adverse incident. Twenty-nine (29.3 per cent) were free from complication in all but one of the observed pregnancies. In the latter group the complications in order of frequency included glycosuria in 8 women, hypertensive disease, postpartum hemorrhage and breech presentation in 4 each, occiput posterior in 3, prolonged labor in 2 and fetal death, maternal sepsis, anemia and preeclampsia in 1 each.

As pregnancies were repeated, the incidence of glycosuria decreased but the incidence of hypertensive disease, fetal death and breech and occiput posterior presentation increased.

The maternal weight tended either to remain stationary or to increase from pregnancy to pregnancy, but there was no observable change in the infant birth weight.

The only patient in the series to have six deliveries at the University Hospitals lost the third and the sixth child. The first pregnancy was without incident. Glycosuria was observed in the second and fourth, but in no other. Hypertensive disease developed during the fifth and resulted in the antenatal death of the infant during the sixth pregnancy. Her weight increased some 50 pounds (23 Kg.) during the period of observation.

COMMENT

There seems to be little doubt that obesity increases the hazards of childbearing. Of these, hypertensive disease is outstanding since nearly one third of the patients suffered from it. Intervention at labor was more frequently necessary and the children were larger

than average. The maternal death rate was twice normal expectancy, but the fetal death rate was not greatly elevated.

Although minor deviations tended toward the abnormal, there were no outstanding departures from normal other than those previously mentioned, namely, hypertensive disease, glycosuria and an increase in the operative incidence, maternal mortality rate and average infant birth weight. This is not entirely in agreement with previous reports.[1] In this connection it should be emphasized that the women of this study were essentially young. One third of them were less than 25, more than one half less than 30 and three fourths under 35 years of age. Obesity with them was not a disease of advancing years but was present from early adolescence. More and more it is becoming apparent that youth is an ally of both primigravid and multigravid women.

Considering the obesity, the fertility of this group was astonishing. Although figures were not analyzed for more than five previous pregnancies, it is possible to say that these women gave birth to at least 2,120 children before coming under observation. Together with the 774 babies born during the period of observa-

tion, there is a total of 2,894 infants produced by 641 obese women, or an average of 4½ apiece. Surely these figures should make one question the often repeated statement that "obese patients are more frequently sterile than women with normal weights." [2]

CONCLUSIONS

1. The incidence of obese women (200 or more pounds) among obstetric patients at the University of Iowa was 1 : 26.

2. The average age at the time of labor was 29.1 years.

3. The incidence of hypertensive disease was 27.4 per cent and of all the toxemias of pregnancy 31.4 per cent.

4. The incidence of breech presentation was slightly increased (5.5 per cent), but otherwise there was no increased rate of abnormal presentation.

5. Operations aimed at delivery were performed in 11.0 per cent of the labors.

6. The average weight of the newborn was 3,580 Gm.

7. The maternal and fetal mortality rates were 0.53 and 4.52 per cent respectively, and the maternal morbidity rate was 12.6 per cent.

8. Ninety-nine women were observed in successive pregnancies. The incidence of hypertensive disease,

ABSTRACT OF DISCUSSION

DR. FREDERICK H. FALLS, Chicago: With the endocrine imbalance which probably accounts for the obesity of a number of these patients, it is not surprising that a glycosuria might be present in an unusual percentage. It would be interesting to know what the sugar tolerance of those not showing glycosuria might be. The relative infrequency of abnormal presentations corresponds with my experience. The conservative treatment based on the uncertainty of diagnosis possibly may have permitted spontaneous correction of some of the malpositions during the early part of the labor, which may give us food for thought in the management of some of the less obese patients. The incidence of postpartum hemorrhage may have been kept to a low level for the same reason. That the children from these women would be relatively heavy is to be expected. It would be interesting to know in this connection what patients delivered prematurely, what at term and what of them went to postmaturity. Also the fact that 85 per cent of these women were able and did nurse their babies at least in part is instructive. The effect of the obesity on the cause of death in the 4 cases described is not at all clear. Case 1 was evidently a nonobstetric death due to pneumonia. Case 2 was due to an error in obstetric judgment in repairing a previously existing third degree tear at the time of delivery. Case 4 might be legitimately charged as an obstetric death, but the propriety of rupturing the membranes when the patient was obviously not ready to go into labor might be questioned. Case 3 must be accepted as an obstetric death. The fact that all these deaths were associated with infection suggests that obesity might have some depressant action on the immunity mechanism of this group of women. The morbidity rate of 12.6 per cent also suggests this possibility. The lesson to be learned from analysis of such a series is that conservative management will give the best results. Most of them will deliver spontaneously or with low forceps if allowed to do so. Watch for toxemia as a cause of overweight. Avoid any manipulation that may introduce infection, because these women stand infection poorly. As a corollary of the last statement give penicillin, if available, and the sulfonamides, if not, prophylactically in adequate dosage to patients even suspected of having infection.

DR. NEWLIN F. PAXSON, Philadelphia: My attention was first drawn to this interesting subject in reviewing for the Philadelphia Maternal Mortality Committee a series of fatalities of hypertension and pregnancy. In a series of cases in Philadelphia it was found that approximately 25 per cent could be labeled as obese; consequently I have been particularly interested in these cases and have observed some of the common abnormalities during pregnancy and delivery. I have observed particularly hypertension and glycosuria as the most common complication during pregnancy. During labor I have observed a high incidence of uterine inertia with poor uterine contractility, which may be one factor in causing prolonged labor. I also have found a higher incidence than usual of abnormal pelves, particularly of the android type, which may account for some forms of dystocia. Post partum I have found a higher incidence of hemorrhage and a greater tendency toward sepsis, so that all cases of obesity that come to our clinic have been listed as potential danger cases requiring particular study and they are held under closer observation than the average. The cases that tax surgical judgment to the utmost are those of spontaneous premature rupture of the membranes before the onset of labor, with a greater incidence of sepsis and a long, slow labor. These are viewed with extreme respect, and I should like to ask Dr. Mengert how he would suggest that such difficult cases be handled.

DR. WILLIAM F. MENGERT, Dallas, Texas: There is an increased hazard with the obese pregnant woman, but we have tried to emphasize that this hazard is not overwhelming, that it is possible for the woman to conceive, to give birth to a great many children and still remain alive. I wonder if endocrine imbalance has a great deal to do with glycosuria in these patients, because it has always seemed to me that pregnancy represents a high function of the endocrine system, and imbalance is usually represented by failure to conceive or go to term if conception takes place. I have felt that in this series we are dealing with young women who enjoy excessive eating and have done so since early adolescence. Regarding case 2 and the error in obstetric judgment in repairing a complete tear post partum, I believe that in many quarters this is accepted practice, and the question that arises is Might not the woman have developed sepsis had her tear not been repaired? There is always criticism concerning the matter of elective, premature, artificial rupture of the membranes, but I should like to point out that in case 4 there was valid indication, since mild toxemia was present, with edema and albuminuria. Regarding Dr. Paxson's question concerning management of a patient with spontaneous premature rupture of the membranes followed by a long latent period, that is an extremely difficult problem. These women are prone to develop infection, and some recent work by the co-author of this paper shows that with sepsis developing before or during labor the fetal mortality rate is alarmingly high. In some 180 such patients approximately 50 per cent of the babies died, chiefly from septicemia or pneumonia. I think that effort should be made to get that patient into labor and then treat her by as conservative obstetric principles as possible. Regarding the high incidence of abnormal pelves in hypertensive women in Philadelphia, I wonder if this has any special association with obesity.

Clinical Notes, Suggestions and New Instruments

PRETIBIAL FEVER

LAURA L. LIPSCOMB, M.D., NEW HAVEN, CONN., AND JEAN L. McMAHON, M.D., MINNEAPOLIS

Pretibial fever, by name, is a new disease. Daniels and Grennan [1] in 1943 reported an epidemic among men in an army camp. An outbreak of a febrile disease with similar clinical features and known locally as "Brushy Creek" fever was described by Bowdoin [2] in 1942 as possibly a new disease entity.

The following case, which clearly falls into this clinical category, is reported because (1) it is unusual in its isolated occurrence, and (2) it presents an additional feature not hitherto noted:

REPORT OF CASE

History.—F. H., a white boy aged 10 years, was admitted to the New Haven Hospital on Aug. 29, 1944 with fever, nausea and pain in the extremities. He was well until two days before admission, when he became feverish and anoretic. A sensation of stiffness of the upper extremities developed and he complained of shooting pains down his arms on motion. The following day the symptoms persisted and the patient was nauseated. During the afternoon there were "stabbing" pains in the lateral aspect of both thighs on walking. On the third day of illness the pain in the extremities was less severe but he remained anoretic and feverish. The family physician examined the child and found spasm of the back muscles and a rectal temperature of 102 F. A tentative diagnosis of acute anterior poliomyelitis was made and the patient was admitted to the New Haven Hospital.

Examination.—At the time of the child's admission his temperature was 103.3 F. and the pulse rate was 96. He appeared

From the Department of Pediatrics, Yale University School of Medicine, and the Children's Clinic of the New Haven Hospital.

1. Daniels, W. B., and Grennan, H. A.: Pretibial Fever, J. A. M. A. 122: 361 (June 5) 1943.
2. Bowdoin, C. D.: A New Disease Entity (?), J. M. A. Georgia 31: 437 (Dec.) 1942.

moderately ill. There was mild injection of the pharynx, spasm of the erector spinae muscles with pain on anterior flexion of the spine, and slight spasm of the hamstring muscles bilaterally. The neck was supple and there was no rash.

The admission total white blood cell count was 8,100, with 71 per cent polymorphonuclear leukocytes, 21 per cent lymphocytes, 7 per cent monocytes and 1 per cent basophils. There was no anemia. The blood Kahn reaction was negative. Rhinopharyngeal cultures contained no pathogens, and blood culture was sterile. There was a transient 1 plus albuminuria, with normal microscopic findings. Lumbar puncture was performed on admission and revealed clear fluid under normal pressure. There were 5 white cells per cubic millimeter, all of which were lymphocytes. Stained smear of the spinal fluid showed no organisms, and cultures were sterile. The spinal fluid contained 52 mg. of protein and 81 mg. of sugar per hundred cubic centimeters. The result of the Lange colloidal gold test was 4555555543. The spinal fluid Wassermann test gave a 4 plus reaction with cholesterinized antigen and no reaction with alcoholic antigen. Lumbar puncture was repeated on the third hospital day and clear spinal fluid containing 5 lymphocytes per cubic millimeter was obtained. Protein was 21 mg. per hundred cubic centimeters and sugar 59 mg. per hundred cubic centimeters. Cultures were sterile. The Wassermann and colloidal gold tests were not repeated at this time. Intracutaneous tests with old tuberculin were negative through 1.0 mg. Agglutination tests for the typhoid-paratyphoid group, brucella, Proteus OX 19 and heterophile antibodies were done on blood samples taken on the fifth, twenty-sixth, sixty-second and one hundred and tenth days after the onset of the disease and were negative.

Course in the Hospital.—During the first two days of hospitalization the patient's temperature ranged from 100.8 to 103.3 F. He remained moderately ill. On the afternoon of the third hospital day (fifth day of illness) he had a chill and his temperature rose to 105.8 F. A blood culture taken at this time was again sterile. Shortly after the chill an exanthem vaguely resembling erythema nodosum and characterized by numerous erythematous, slightly raised, nontender lesions was observed over the pretibial surface of both legs. The lesions varied in size from 1 by 1 to 2 by 2 cm. except in areas where they were coalescent. The involved areas felt warmer than the adjacent normal skin and blanched on pressure. On the following day (sixth day of illness) the rash persisted and a few similar lesions were observed on the posterior and lateral aspect of the legs and the distal, anterior aspect of the thighs.[3] The temperature remained elevated between 102.2 and 106 F. and the spleen became palpable. On the seventh day of illness the patient was essentially afebrile until in the evening, when the temperature rose and remained between 100 and 102.2 F. during the following two days. The rash had faded considerably on the seventh day but on the eighth was more brilliant than ever. Subsequently it faded and was not apparent after the ninth day. There was no associated inguinal lymphadenopathy, and an enanthem was never observed. The patient became afebrile on the tenth day and remained so. He was discharged home two days later. The spleen was not palpable at this time.

The patient was examined in the Pediatric Dispensary of the New Haven Hospital on the twenty-sixth, sixty-second and one hundred and tenth days after onset of the disease. On each occasion he appeared well and was asymptomatic, and physical examination revealed no abnormality. Total blood leukocyte counts were 3,600, 7,000 and 7,600 per cubic millimeter respectively. On the one hundred and twenty-eighth day after the onset of the disease the patient returned for repeat lumbar puncture. Clear spinal fluid containing 2 lymphocytes per cubic millimeter was obtained. Protein was 21 mg. per hundred cubic centimeters, sugar 52 mg. per hundred cubic centimeters and chloride 127.6 milliequivalents. Colloidal gold and Wassermann tests were negative.

The parents and 3 siblings of the patient remained well. There was no known similar disease in the locality.

3. The diagnosis of pretibial fever was first suggested by Dr. Dorothy Horstman of the Section of Preventive Medicine, Department of Internal Medicine, Yale University School of Medicine.

COMMENT

The case presented is a classic example of pretibial fever. Daniels and Grennan[1] first described this disease by name in their report of an epidemic febrile illness which occurred in 40 soldiers at Fort Bragg, North Carolina. It was so named because the most striking finding was an erythematous, nonpetechial rash which appeared about the fourth day of illness and which was solely or predominantly pretibial in distribution. Other typical features were abrupt onset, myalgia, splenomegaly, bradycardia and leukopenia. The etiology and mode of transmission of the disease could not be determined despite extensive studies.

Previously Bowdoin[2] in 1942 reported an outbreak of a febrile illness which he considered to be a new disease entity and which may have been pretibial fever. The general clinical picture in these cases was compatible with this diagnosis. An

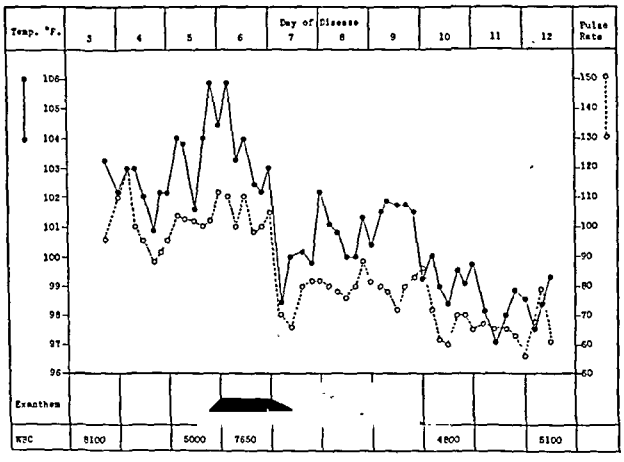

Fig. 1.—Clinical course of patient during period of hospitalization.

exanthem was observed in only 9 of the 35 cases, but in 8 cases it was solely pretibial in distribution.

At the present time the diagnosis of pretibial fever must be made on the basis of history, physical findings and clinical course. The nature of the morbid process may well remain an enigma until the appearance of the characteristic rash.

Also, in the absence of the typical exanthem, sporadic cases cannot be recognized. It should be mentioned in this connection that Greenfield[4] described as an example of pretibial fever a case in which the rash was atypical as to type and distribution and which presented other such unsual features as generalized lymphadenopathy and pneumonitis with fatal termination.

If a diagnostic test becomes available, less clinically obvious cases may be included as examples of pretibial fever. For that matter, the possibility exists that pretibial fever is not a specific disease entity. In the meantime this clinical classification tends to focus attention on such cases so that they can be studied in more detail.

SUMMARY

A case of pretibial fever, observed in a 10 year old boy, was unique in its isolated occurrence. Though some of the previously reported cases have shown nuchal rigidity, this is the first in which abnormalities of the spinal fluid have been found, namely increased protein content and positive colloidal gold and Wassermann tests.

CORRECTIVE CAST FOR TREATMENT OF LOW BACK PAIN

EMIL D. W. HAUSER, M.D., CHICAGO

Low back pain, in most cases, is due to a strain which causes an inflammation in the region of the lumbosacral and sacroiliac articulations. Strain is the result of an imbalance between the capacity of the structures of the back and the physiologic demands made on them. This imbalance is called a functional decompensation. A decompensation of the back gives rise to certain symptoms and findings.

The symptoms are low back pain and tiredness; this fatigue of the back is often associated with a general fatigue. The first pain noted is usually generalized and is in the muscles, with associated stiffness on arising after rest. Later the pain localizes and may involve the lumbosacral angle or the sacroiliac joint. In the acute phase of this condition there is a sudden "catch," associated with lumbar muscle spasm, loss of the lumbar curve, a protective list with a pelvic tilt, limitation of motion in the lumbar area and a positive Laségue sign. Paresthesia along the course of the sciatic, lateral cutaneous and gluteal nerves is a frequent complication. This is a referred

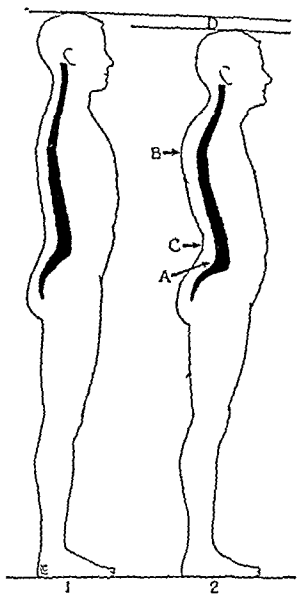

Fig. 1.—Good posture with normal anteroposterior curves.
Fig. 2.—Poor posture with increase of anteroposterior curves.

pain due to repeated stimuli caused by the strain and inflammation of the joint with a low threshold of the nervous system. Decompensation causes a sagging of the back with an increase of the normal curves, dorsal kyphosis and lumbar lordosis. The lumbosacral angle becomes more acute and the shearing force is increased. This produces strain on the lumbosacral and sacroiliac joints, with inflammation of the ligaments and articular surfaces.

The treatment of low back pain, therefore, consists in correction of the deformity, relief of the strain at the sacroiliac and lumbosacral joints and elimination of the decompensation of the back. This is accomplished by means of a so-called active cast. An active cast is one which is applied with the body in a position such that the natural forces of the body will act against the cast. In this way the cast has the effect of exerting a corrective force. To correct the dorsal kyphosis I consider first that 20 per cent of normal motion is in the dorsal area and 80 per cent in the lumbar area. Therefore the dorsal curve is more fixed than the lumbar curve. With the pelvis held in the normal position and the patient bending forward, the lumbar curve can be brought to any desired position. The lumbar curve could be fixed in the normal position by means of a plaster of paris cast applied with the body bending forward. Since the body will always assume the upright position, owing to the self-righting reflex (Sherrington), the natural forces of the body will act against the cast to correct the dorsal kyphosis.

A further analysis of the forces involved in such a corrective cast follows. Figure 1 shows the position and shape of the spinal column in a normal human body. The column is kept

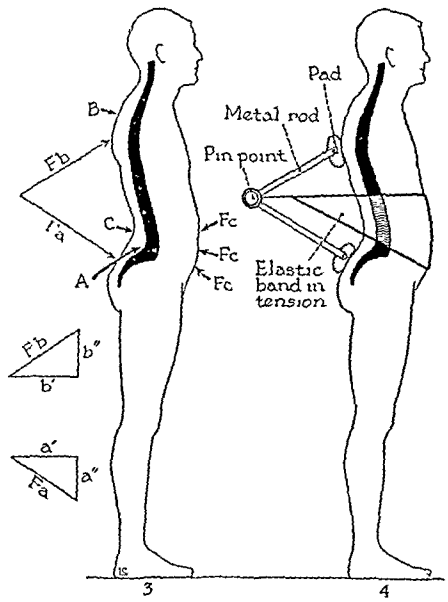

Fig. 3.—Force vectors applied to correct postural defects.
Fig. 4.—A theoretical device for correction of postural defects.

erect by the action of the muscles of the back, abdomen and chest. The action of these muscles is similar to that in a segmented tent pole which is kept erect by the action of many guy wires. If the muscles are not able to function normally, the body will sag in the direction of the curves already present. An incorrect posture, as seen in figure 2, will result. Since the lumbosacral angle has been decreased, the shearing force at this point is greater. Furthermore, the increase of the dorsal and

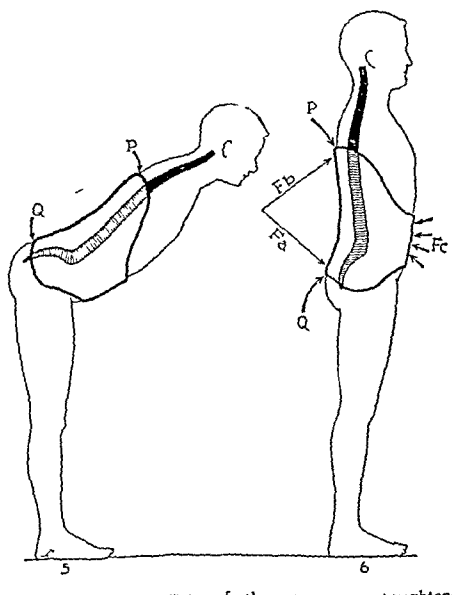

Fig. 5.—Anteroposterior curves of the spine are straightened when trunk is flexed. Plaster cast applied in this position.
Fig. 6.—Force vectors applied to correct postural defects when upright position is assumed in plaster cast.

lumbar curves results in a decrease in the height of the person. This decrease must be accompanied by more strain on the ligaments at the lumbosacral and sacroiliac joints. To correct these mechanical defects, the forces are applied as in figure 3. The

two forces *Fa* and *Fb* are concentrated in their application, while the total force *Fc*, acting on the abdomen, is distributed over a large area, and thus the pressure at any one point is not too great. For this reason the forces *Fa* and *Fb* are represented by single vectors, while the total forces in the abdomen are broken down into smaller forces over the area. All of the forces acting on the body are in equilibrium. The two forces *Fa* and *Fb* have components acting vertically away from each other, which put the spine in vertical tension and thus straighten it. The forces *Fa* and *Fc* act against each other and work toward removing the sag and reducing the shearing force. The dorsal curvature is corrected by the action of the horizontal component *Fb*. When the body assumes the upright position, the self-righting reflex acts against the force *Fb* to correct the dorsal curvature. A device which will apply the forces just described is shown in figure 4. Two rigid bars are used to apply the forces *Fa* and *Fb* respectively. To put these bars in compression, an elastic strap is applied as shown in the illustration. The strap passes over the abdomen, applying the distributed forces *Fc*. This device would apply all three forces necessary to correct the poor posture.

A practical application of this device is obtained by means of a plaster of paris cast, as seen in figure 5. With the patient bending forward and with extension on the head, curvatures of the spine are decreased. When the cast is applied to the lumbar spine and pelvis this curve becomes fixed, with the patient bending forward. When the patient stands upright (self-righting reflex), in effect the forces are applied as seen in the illustration with the elastic band device (fig. 4), with one important difference. In the elastic band device the variable force was applied by the band and the patient would have no control of the forces acting on him. In the plaster cast the patient actually applies the force on himself. After the cast is applied and the patient assumes the upright position (fig. 6) the back is longer than before. The height of the patient has been increased. Therefore when the patient is tired he will sag, but the body weight will come to rest on the top of the cast and be transmitted onto the pelvis, relieving the strain on the lumbosacral and sacroiliac joints. Thus the cast exerts forces to correct the deformity of the back and at the same time relieves the strain on the joint so that the inflammation can subside. Since the trunk is extended and the body is higher than before the application of the cast, more work is required to hold the upright position. This brings about an increase in the demand on the muscles, which acts to strengthen these structures. This increase in strength is further abetted by means of graduated exercises, alternated with periodic rests to prevent muscular strain.

The treatment is ambulatory, and relief is obtained at the same time that correction is taken. Pressure sores are not encountered.

This treatment by active cast has been applied in 2,626 cases. Excellent results were obtained in 35.6 per cent of the cases. This meant complete and permanent relief of symptoms under all circumstances. In 58 per cent of the cases the results were good. These patients were relieved of their symptoms and were satisfied but felt occasional aching or tiredness as a consequence of excessive strain. There were fair results in 3.4 per cent of the cases. These showed definite improvement but did not have complete relief of all their symptoms. Those who were not satisfied were considered poor results and composed 3 per cent of the cases.

SUMMARY

1. Low back pain is frequently due to an imbalance between the demand made on the back and the capacity of the back to do the work required of it.

2. In addition to the symptoms of low back pain, fatigue, soreness and stiffness in the back, the decompensated back has an altered posture. The normal dorsal and lumbar curves are increased.

3. The lumbosacral angle is more acute, increasing the shearing force.

4. The body sags, putting strain at the lumbosacral and sacroiliac joints, with the resulting inflammation of these joints.

5. A cast can be applied to correct the position, decrease the strain on the lumbosacral and sacroiliac joints and increase the capacity of the back.

6. A statistical study of 2,626 cases in which the corrective cast was applied showed excellent results in 35.6 per cent of the cases, good results in 58 per cent, fair results in 3.4 per cent and poor results in 3 per cent.

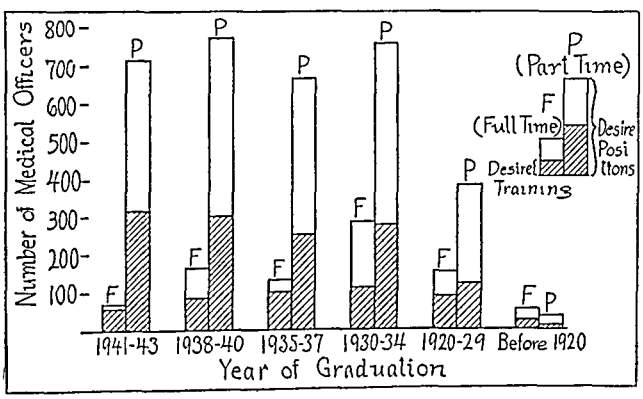
THE MEDICAL OFFICER AND FUTURE INDUSTRIAL MEDICAL PRACTICE

LIEUTENANT COLONEL HAROLD C. LUETH
Surgeon General's Liaison Officer
MEDICAL CORPS, ARMY OF THE UNITED STATES

Interest in the practice of industrial medicine has been constantly growing among the medical profession. Since the war started there have of necessity been certain changes, especially a curtailment of qualified personnel. For purposes of future planning it is desirable to have an estimate of the likely status of industrial health in the future.

The Committee on Postwar Medical Service made a study of the future desires of medical officers. At the time the committee devised its questionnaire, arrangements were made for the inclusion of questions concerning industrial practice. A pilot questionnaire mailed to 3,000 medical officers included a number of questions concerning industrial practice; in the response to this inquiry a small number of men indicated interest in the several fields of industrial practice. A final questionnaire was later prepared and distributed to each medical officer on active duty with the Army, Navy, Public Health Service and Veterans Administration. Owing to limitations of space and the indicated limited interest in industrial health compared to other features of general medical practice, the section on industrial practice of the questionnaire was brief.



The first question asked was "Would you wish a position in industrial medical practice?" One fourth of all men, or 4,215 who returned questionnaires, indicated that they were interested in the industrial field. There were 863 men who wanted full time positions and 3,352 men who wanted part time positions. Requests for full time positions in industrial practice were scattered among the different graduation groups. For example, there were 73 requests from graduates of 1941 to 1943, 164 from graduates of 1938 to 1940, 136 from graduates of 1935 to 1937, 285 from graduates of 1930 to 1934, 153 from graduates of 1920 to 1929 and 52 from graduates of before 1920. About 80 per cent of the total, or 16,579 medical officers, definitely indicated that they were not interested in industrial practice.

Another question asked was "Would you wish special training to qualify for such a position?" Medical officers who would like to have full time positions in industrial medicine were about equally divided; there were 484, or 56 per cent, who wanted special training, and 379, or 44 per cent, who did not want special training. The greatest number of requests for special

training came from the youngest graduates. The other graduation groups were about evenly divided between those who wanted special training and those who did not. The following numbers of requests came from the several graduation groups: 59 from group 1, 88 from group 2, 99 from group 3, 118 from group 4, 95 from group 5 and 25 from group 6.

About four times as many men wanted part time positions in industrial medicine as wanted full time positions. Requests came from about the same number of men in each of the first four graduation groups. There were 716 requests from graduates of 1941 to 1943, 773 requests from graduates of 1938 to 1940, 672 requests from graduates of 1935 to 1937, 768 requests from graduates of 1930 to 1934, 388 requests from graduates of 1920 to 1929 and 35 requests from graduates of before 1920.

A little more than one third of the men who would like to engage in part time industrial medical practice would also like to take special training to qualify for positions. Nearly the same ratio of men who wanted special training to the total number in the graduation

Analysis of 21,029 returned questionnaires with respect to future desires of officers concerning industrial medical practice and training.

group was observed in each of the six graduation groups. Requests for special training came from 311 officers of group 1, 299 of group 2, 233 of group 3, 274 of group 4, 130 of group 5 and 52 of group 6.

There were 235 medical officers who were undecided about future work in industrial health, among whom 65 definitely requested further training.

Special courses in industrial health were requested by a total of 1,809 medical officers. They included men who desired full time positions in industrial medicine, men who desired part time positions in industrial medicine and men who were undecided about future positions in industrial medicine. The following number of men made requests: 381 from graduates of 1941 to 1943, 405 from graduates of 1938 to 1940, 346 from graduates of 1935 to 1937, 408 from graduates of 1930 to 1934, 231 from graduates of 1920 to 1929 and 38 from graduates of before 1920.

The questionnaire was divided into six parts: (1) general information, (2) educational, (3) industrial, (4) practice and licensure, (5) economic and (6) additional information. On the front of the questionnaire the educational portion occupied three fourths of the page, and it listed different types of training, such as internship, residency, fellowship, review courses and "other." It also listed a number of special forms of medical practice. As a result there were a number of men who entered their desire for additional training in industrial work under the educational portion of the questionnaire.[1] They naturally represented a much smaller group than those who indicated their desire for special training under the industrial section, since the questions under the latter section focused attention on the possibilities of future training and practice.

Under the educational section there were 34 requests for training in industrial medicine; of these, 21 men wanted short courses and 13 wanted long courses. There was one request for insurance training.

Short Courses.—Requests came from 3 graduates of group 2, 4 of group 3, 9 of group 4 and 5 of group 5, and most of them were for unspecified periods of training. Almost all of them had been on active military duty for two or more years.

Long Courses.—Thirteen medical officers requested training in industrial medicine and 1 in insurance work. Nearly all who wanted future training in industrial medicine were graduates before 1934 and preferred courses of six to twelve months. About half the men were in industrial practice before entering the military service; the other half were formerly in private medical practice. The request for insurance training came from a 1942 graduate who entered the Army from internship and who wanted a two year course.

Returns from the final questionnaires indicated that about 4 per cent of men in each graduation group, except group 1, wanted full time positions in industrial medicine. There were only 1.7 per cent of the medical officers in graduation group 1 who were interested in full time industrial positions. From the pilot questionnaire [2] it was shown that more than seven times as many men desired a university course of training as desired training in industry. The study also revealed that the major fields of interest were industrial surgery, insurance and plant medical department work. From this it appears that those interested in furthering sound future industrial medical practice should seek to interest younger medical officers by acquainting them with opportunities along the line of university training supplemented by in-service training in industrial plants.

Since the various aspects of industrial medical practice will be most influenced by the character and number of physicians who engage in its full time practice, encouragement of sufficient numbers of younger men in the field among whom the more capable may be selected for thorough training in its different aspects is the best assurance of meeting the objectives of good industrial medical practice in the future.

Over 16 per cent of the medical officers in each graduation group wanted part time positions in industrial medicine. While physicians engaged in part time industrial medicine render important service concerning care of patients, it is doubtful that they exert much influence on the future development of the field. Many men engaged in part time industrial practice are interested in the financial returns and view the positions as an economic security and are only secondarily concerned with future developments of sound, high grade industrial medical practice. Improved training facilities in both universities and industry and the selection of the more qualified younger men for full time positions, it is believed, will be instrumental in the development of improved industrial medical practice both for full time and for part time practitioners.

Council on Foods and Nutrition

SPECIAL ARTICLE

This is the fourth of a series of articles discussing the significance of protein nutrition in health and disease. This material was prepared by the authors at the request of the Council and has been authorized for publication

GEORGE K ANDERSON, M D, *Secretary.*

PROTEIN IN SURGERY

CHARLES C. LUND, M D.
AND
STANLEY M. LEVENSON, M D.
BOSTON

During the period of great expansion in surgery that followed the introduction of anesthesia and of asepsis, surgeons focused their attention on anatomy, surgical technic, pathology and bacteriology Early it was seen that patients who could not survive complete operations might survive multiple stage operations if the first stage was a simple procedure that relieved an interference in some vital function. After such procedures a period of rest and good nutrition frequently resulted in improvement in the patient's health, so that he could survive the more serious curative operation at the second stage. Studies were not made of the optimum diets to use in the interval between operations.

Recently new methods of study and treatment of nutritional deficiencies, including protein deficiencies, have been developed. The opening article in this series, by Stare and Davidson,[1] reviews the modern knowledge of protein nutrition. The correction of protein deficiencies is of importance in shock,[2] in local [3] or general [4] hypoproteinemic edema, in wound healing,[5] in immunity to infection [6] and in detoxication of poisonous substances.[7] The methods of treatment include the use of whole blood, plasma and albumin for acute deficiencies such as hemorrhagic shock; protein hydrolysates, concentrates and diets for less acute and for chronic deficiencies.

THE CAUSES OF PROTEIN DEFICIENCY IN SURGICAL PATIENTS

The subject of nitrogen balance has been discussed previously in this series.[8] This discussion will therefore be limited to the importance of those causes of protein deficiency not including chronic dietary deficiencies, or failure of formation of protein due to liver disease, that are seen especially in surgical practice, although the surgeon must realize that the most important and frequent factor in protein deficiency is inadequate intake of food. Losses of protein may be from the intestine, through the kidneys, from any wound or orifice of the body, in internal exudates and transudates, and from any pathologic condition of the skin that causes oozing or desquamation. In general, losses from the intestine are important only in the presence of copious or long continued bleeding, diarrhea or vomiting, or due to the feeding of diets containing large amounts of roughage, and, from the urine, in the period of the increase in protein catabolism that follows injury or infection or in the nephrotic syndrome.

Coincident with the early effects of any acute trauma, poisoning, infection or even of unusual extreme exercise, a large output of nitrogen may occur in the urine that lasts for many days or even weeks. Surgical or traumatic shock does not necessarily form a part of this picture. A large part of this output of nitrogen in burns may be in the form of "undetermined" nonprotein nitrogen [9] rather than of the substances such as urea that are usually found in the urine. Satisfactory chemical characterization of the compounds excreted has not been made. Cuthbertson [10] found that nitrogen losses in the urine after fractures reached 25 Gm. per day and remained high for many days. *Elman* [11] found losses of similar magnitude after surgical operations. Lucido [12] and Taylor [9] found similar large losses following burns. In one of Taylor's cases there was a loss of 45 Gm. of nitrogen in one day. Browne [13] has found that a negative nitrogen balance may last up to forty-five days after some injuries. Important losses from wounds occur only in wounds of large size with large quantities of discharge such as are seen in osteomyelitis, chronic pleuropulmonary infection, other severe chronic infections or chronic bleeding. Important losses of nitrogen from the skin are commonly seen only in deep burns of large area, but in these the losses may be extreme and may continue over long periods of time. Early after superficial burns there is a large output of plasma-like fluid through the skin. This contains a high proportion of protein.[14] Later, during the sloughing stage of deeper burns there is a steady and severe loss of protein in the form of purulent material from the bed of granulations. This loss has been estimated by Taylor [15] and measured by Hirshfeld [16] and Co Tui.[17] They find that these losses may reach many grams of nitrogen per day, and the amount of loss varies directly with the area involved. These losses continue until healing is complete. Co Tui [18]

Drs C. S. Davidson and F. H L Taylor made many helpful suggestions and criticisms.

From the Burn Assignment of the Surgical Services and the Thorndike Memorial Laboratory of the Boston City Hospital and the Departments of Surgery and Medicine, Harvard Medical School The work described in this paper was done, in part, under a contract recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Harvard University.

has also measured similar losses in wound exudates and from tube drainage of the upper gastrointestinal tract. These losses from surfaces and wounds have not, in the past, been considered in calculating conventional nitrogen balances, and therefore it must be realized that errors of great magnitude may be introduced into such studies unless this factor is considered. A good discussion of this subject is to be found in Taylor's [15] paper.

At the same time at which large quantities of nitrogen are being lost in the urine and from wound drainage of such patients, the protein intake is likely to be greatly reduced by reason of pain, anorexia and poor or absent gastrointestinal function. The negative nitrogen balance occurring under these conditions may have serious effects in a few days [19] in the patient with already depleted body protein, and in a few weeks [15] in a patient with excellent protein nutrition.

Casten [20] has found hypoproteinemia to be associated with anesthesia. Although the studies have not been carried far enough to determine whether protein lost from the blood stream in anesthesia is excreted or merely shifted temporarily into the tissues, he found a steady reduction in the protein level in the plasma with any anesthetic agent. If the liver function was impaired preoperatively as demonstrated by a hippuric acid test, reduction of plasma proteins followed even after short operations. Further studies of this effect of anesthesia are indicated.

RESULTS OF PROTEIN DEFICIENCY ON SURGICAL PATIENTS

Hypoproteinemic edema occurs in surgical patients only when the protein depletion is extreme. However, depletions of lesser severity may cause interference with the healing of surgical wounds and burns and with gastrointestinal function before and after operations and may be an important factor in the cause of gastrointestinal, leg and decubitus ulcers. Depletion of protein also may predispose a patient to various forms of shock and reduce the resistance to infection. For these reasons the protein deficient individual is a poor operative risk.

Edema.—The first publication indicating the importance of protein nutrition in the surgical patient was that of Jones and Eaton,[4] who found that edema due to hypoproteinemia was common in patients before and after gastrointestinal surgery and that it was usually associated with a prolonged inadequate food intake. When such patients were given the then customary large quantities of saline infusions by vein postoperatively, acute pulmonary edema frequently occurred and was often fatal. They showed that this danger could at times be obviated by substituting glucose in distilled water for a large part of the glucose in saline solution that was given postoperatively. This finding has been amply confirmed by others. Jones [3] and Ravdin [21] have shown also that local edema at the site of an operation may occur in the presence of hypoproteinemia but without generalized edema. This edema may result in obstruction of the stoma of a gastrointestinal anastomosis and may, unless corrected, result fatally. Meyer and Kozoll [22] have also reported poor function of anastomoses from this cause. Minot [23] has emphasized the vicious cycle that occurs under these conditions.

Wound Healing.—Clark [24] showed that a low protein diet increased the "lag" period in the healing of experimental wounds in dogs. Harvey and Howes [25] compared the healing of experimental wounds of rats fed a standard maintenance diet which was low in protein with the healing of the same wounds of rats fed a very high protein diet. They found much more rapid healing in the rats on the latter diet and stated that this diet stimulated healing. One could also state that these experiments showed that one or more deficiencies in the low protein diet delayed normal healing. Howes and McKeown [26] studied the healing of fractures in rats in the same manner and found the same results. They also found that the bones of the rats receiving the low protein diet broke after less force was applied to them than did the bones of the rats receiving the high protein diet. It was, however, as recently as 1938 that Thompson [5] showed that human wound healing was also adversely affected by hypoproteinemia. He found a high incidence of postoperative wound disruption in hypoproteinemic patients compared to a low incidence in normal patients. Koster and Shapiro,[27] Hartzell,[28] Koster and Kasman [29] and Meyer and Kozoll [22] have confirmed this observation. Depleted protein stores have been associated with failure of skin grafts.[30] However, it should be emphasized that low protein diets imply much more than mere protein deficiency, as low protein diets are, unless special precautions are taken, usually low vitamin diets and several vitamins, particularly riboflavin, ascorbic acid and vitamin A, are growth factors and therefore associated with healing.

Gastrointestinal Function.—Jones [3] and Mecray [31] showed that hypoproteinemia prolonged the emptying time of the stomach, and Barden [32] showed impaired small intestinal function from the same cause. These findings have been confirmed by others.[22] Jones [3] and Ravdin [21] have also shown that surgical gastric stomas are particularly prone to become edematous in the presence of hypoproteinemia. When this happens, complete obstruction of the stoma may occur. Further surgery to relieve such an obstruction is dangerous and usually ineffective. Reduction of the intake of sodium has alleviated this edema promptly in some cases.[33] Theoretically, human albumin given intravenously should be useful in such an emergency.

33. Jones.[3] Jones and Eaton.[4] Ravdin, Stengel and Prushankin.[21]

Gastric and Duodenal Ulcers.—Three sets of experiments show that a low protein diet will always cause an ulcer in the forestomach of rats [34] and in the stomach of dogs [35] in a very few days. Jones and Eaton [4] and many others have shown that human gastroduodenal ulcers are frequently associated with hypoproteinemia. An exceedingly important observation is that of Co Tui,[36] who finds that a more striking remission of gastroduodenal ulcers follows treatment with a very high protein, high caloric diet than follows the conventional Sippy diet. All of the protein in his diet is given by mouth in the form of an enzymatic hydrolysate of casein and pancreas. He gives from 0.5 to 0.8 Gm. of nitrogen per kilogram of the patient's weight and a total of 40 to 50 calories per kilogram. The Sippy diet is quite different. In the first stage it is frequently made up of milk and cream; 39 ounces of this mixture gives only 35 Gm. of protein and 1,535 calories, of which two thirds are contributed by fat. For a 70 Kg. man the Sippy diet would furnish only one sixth the amount of protein and one half the calories that are furnished in Co Tui's minimum diet. The usual Sippy regimen later increases the protein intake to a little over double the original figure, but even after this increase neither the protein intake nor the caloric intake approaches those of Co Tui's diet.

Chronic Ulcers of the Skin.—Altschuler [37] has treated patients with skin ulceration, particularly those resulting from phlebitis or varicose veins, with protein hydrolysates. He frequently found that hypoproteinemia was present in these cases and that the ulcers healed rapidly when this was corrected. Mulholland [38] studied a large number of patients with decubitus ulcers and also found this type of ulcer to be universally associated with hypoproteinemia. Healing was rapid after an adequate protein intake was furnished.

Surgical, Traumatic, Hemorrhagic and Burn Shock.—A condition associated with hypoproteinemia is a reduced blood volume. The shock connected with surgical procedures, trauma, hemorrhage and burns is associated with reduced blood volume. Hypoproteinemic animals have been shown to be particularly susceptible to shock after any kind of injury. Whipple [39] long ago reported experimental shock from hypoproteinemia in plasmaphorized dogs. More recently Elman [40] has shown that in the presence of hypoproteinemia shock develops from very slight losses of blood and that, following such losses, a great decrease in the already low plasma protein concentration ensues.

Resistance to Infection.—Madden [41] showed that hypoproteinemic dogs were very susceptible to infection and that, once infection had developed, the regeneration of plasma protein was much more difficult. A study of the greatest importance to surgeons has recently been made by Cannon,[6] who studied the formation of antibodies in hypoproteinemic rats and found that under such circumstances their production was much reduced as compared to their production by normal rats. He gives a brief history of a patient whose plasma protein level was very low and who developed postoperative peritonitis and expresses the belief that the occurrence and outcome of various postoperative infections, including pneumonia, depend in large part on the titer of immune substances in the body, which in turn depend on the nutritional status of the patient.

Liver Damage.—It has recently been shown, in animals, that in the course of protein depletion the liver loses protein,[42] decreases in size [43] and becomes soft [44] and fatty.[45] In presence of hypoproteinemia such conditions as biliary obstruction,[46] chloroform anesthesia [47] and arsphenamine treatment [48] cause much more injury to the liver cells than they do in the well nourished patient (biliary obstruction) or well nourished animals (all three conditions). Conversely, the injured liver cannot manufacture albumin [49] or prothrombin [49] as well as the normal one. Thus it is seen that another vicious circle is encountered because the damaged liver cannot carry out its normal function of manufacturing proteins that it normally furnishes to the blood and which, in turn, protect it against damage. Although most of this work has been done on animals, it is likely that the human liver reacts in a similar fashion. However, one must remember again that the patient with hypoproteinemia may have important deficiencies other than protein which may affect the liver adversely.

FREQUENCY OF PROTEIN DEPLETION IN SURGICAL PATIENTS

1. *Prior to Operation or Injury.*—Jones and Eaton [4] found that hypoproteinemia was common among their patients with gastrointestinal disease coming to operation. Mulholland [38] has found this condition universally present in his cases of decubitus ulcers. Altschuler [37] found it commonly in ulcers of various types. Hartzell [28] found many instances in general surgical cases. Thornton [50] did not find this common in patients coming to thoracic surgery. Bartels [51] and Brown and Mecray [52] found it very common among the most severely affected group of hyperthyroid patients but less common in those

mildly affected. The group at the Memorial Hospital [53] found it common among cancer patients. In a study of 278 patients Meyer and Kozoll [22] found it frequently in association with a wide variety of surgical conditions, but in some instances the hypoproteinemia developed during acute illness or postoperatively. Evans and Boehme [54] have also found hypoproteinemia very common in general surgical patients. From these references it is seen that hypoproteinemia is to be expected frequently in a wide variety of conditions.

2. *Subsequent to Operation or Injury.*—Thornton,[50] who found essentially no hypoproteinemia prior to thoracic operations, observed that, in spite of careful replacement of the total amount of blood lost at operation, there was an average decrease of plasma protein concentration of 1 Gm. per hundred cubic centimeters in 31 of 32 patients within the first week postoperatively. Meyer and Kozoll [22] found a drop of 25 per cent of the plasma protein after operations for carcinoma of the colon and for intestinal obstruction. Ariel [55] found a greater fall in plasma protein in patients with cancer of the gastrointestinal tract than in other patients. He felt that this occurred because their protein stores were more depleted. Many groups studying burns [56] have found decreases to 3.0 to 5.0 Gm. per hundred cubic centimeters of plasma protein following severe burns even in some in whom strenuous measures to combat the fall were made. Losses of weight are frequently an indication of depleted protein stores and great losses following injury, operation and burns have been reported by Cuthbertson,[10] Hirshfeld,[16] Elman,[19] Levenson [30] and Lyons.[57]

THE EVALUATION OF PROTEIN DEFICIENCY IN SURGICAL PATIENTS

The estimation of the status of a surgical patient with regard to the presence or degree of protein deficiency is not simple. The factors necessary for a critical evaluation are (1) *optimum* weight of patient, (2) observed weight of patient, (3) plasma protein level, (4) plasma albumin level, (5) plasma volume, (6) nitrogen intake and (7) nitrogen output. Actually, main reliance in clinical work has to be placed on a nutritional history, on the patient's weight and on serum protein content determinations done most simply by a densitometer method. Interpretation of serum protein concentration values is often difficult. In surgical patients, particularly, one is frequently confronted by situations in which an acute disturbance has occurred in a patient with chronic protein deficiency. When this happens, the acute changes may intensify or mask the chronic ones, depending on the direction of change. A patient who has depleted body proteins and normally a low plasma protein level may by reason of vomiting become dehydrated. Plasma protein concentration may then become normal. However, as the blood volume of such a patient is increased by the administration of solutions of electrolytes or by other means, the plasma protein concentration will be found to fall to low values. Drew,[58] Seaman and Ponder [59] and Abbott and Mellors [60] have studied this problem and have shown how to make close evaluations of the true protein status of the patient in a short time by a few serial observations during treatment. Butler and Talbot [61] have reviewed the literature on the problems of parenteral fluid therapy and presented the best discussion of the evaluation of these patients.

The relative changes of albumin and globulin are also a factor of importance. In general, in acute depletions from any cause the albumin is lost faster and to a greater amount than the globulin and is built up again more slowly. A normal plasma protein value will mask a quite severe hypoalbuminemia when the globulin level is high. It must be remembered that except in acute loss the plasma proteins fall only after long continued depletion. Therefore, in cases of chronic illness the presence of a hypoproteinemia indicates a large tissue protein deficit. Elman [62] finds that a loss of 1 Gm. of albumin from the plasma represents a tissue loss of 30 Gm of protein. Still higher ratios of plasma to tissue protein have been found.[63]

Elman [19] stresses loss of weight in evaluating protein depletion. Serial determinations of the weight of patients with burns have been found to be of great value. The weights of these patients may be secured at each dressing change by putting the patient, covered with a sterile sheet but with dressings removed, on a weighed stretcher each end of which is placed on a scale. Slight changes of weight are often the first indication that the patient's nutritional condition is getting better or worse.[64]

When a surgeon first starts to weigh his patients he may be astounded at the losses encountered. Losses of 1 to 1½ pounds (454 to 683 Gm.) a day are common after major operations, major injury, serious infection or burns when the patients receive the customary postoperative care. These losses may continue for as long as the patient is seriously ill unless special efforts are made as outlined here to prevent them. Losses of over 50 pounds (23 Kg.) in a few weeks have been reported in burns [15] and of 11 to 66 pounds (5 to 30 Kg.) after infected wounds [57] and up to 25 pounds (11 Kg.) after a relatively uncomplicated cholecystectomy.[19] Elman also finds an appreciable loss of weight after any surgical operation.[19]

THE TREATMENT OF SURGICAL PATIENTS WITH HYPOPROTEINEMIA

Chronic Conditions.—Whenever possible, protein losses or deficiencies should be corrected by oral feeding. It is not enough for the surgeon to order a "high

protein, high caloric, high vitamin diet." If such a diet is ordered the patient may fail to benefit from the order for any one of the following reasons: 1. The diet presented to the patient is not as specified. 2. The diet presented is not eaten in whole or in part because it lacks palatability, there is lack of appetite and there is a lack of nurses to encourage eating. 3. Food eaten may be partly or wholly lost because of diarrhea or vomiting.

These difficulties have been encountered frequently in caring for patients with burns during the last two years.[65] The fact that item 1 is mentioned may be a surprise. What especially happens in these days with the shortage of nurses is that there are frequent times when supplementary feedings are not brought to the patient because the nurse has other duties to perform that she thinks are more important or more urgent. This is particularly likely to happen at night.

The three items listed under number 2 are interrelated. It is common experience to find that a sick patient has "no appetite." However, if special attention is paid to the likes and dislikes of the patient and special or other nurses are available to encourage eating and to offer meals when the patient desires them instead of only at stated routine periods, many such patients will eat a surprisingly large amount of food. A patient with severe but not desperate third degree burns had special nurses for the first two weeks and had a daily nitrogen intake of 25 Gm. with a caloric intake of 1,800. During the next eleven days, without special nurses, her nitrogen intake fell to 6 Gm. and her calories to 1,600. Later, by employing special nurses again, the nitrogen intake went up to 40 Gm. with 3,500 calories.

The two items under number 3 are also related to each other. Forcing the diet in a sick patient does not always result in a net gain. Nausea, vomiting, distention and diarrhea, singly or together, are limiting factors. In general, the sicker the patient the less fat is tolerated, and the larger the proportion of protein should be. It has been found that at least 25 per cent of the calories in the diet should come from protein and not over 15 per cent from fat if any of these intestinal symptoms have occurred recently. It is well to take a number of days to increase the food intake, as sudden increases are more likely to be followed by gastrointestinal symptoms, which can usually be avoided by more cautious increases. If this diet is not tolerated, protein in the form of a digest may be tried and frequently will be well tolerated. The available digests are not particularly palatable and should be given by intubation.

Supplementary Feeding Formulas

Type of Case	Method of Feeding	Constituents of Diet	Carbohydrate, Gm.	Protein, Gm.	Fat, Gm.	Calories, Gm.
Severe chronic burn	Oral	House diet	40	55	40	740
	Oral	Skim milk powder...100 Gm. Chocolate syrup..... 90 cc. Whole milk..... 1.0 liter	180	65	40	1,340
	Tube	Amigen, oral *.....300 Gm. Nutramigen **.....150 Gm. Water..... 3.0 liters	80	255	25	1,565

Severe acute burn	Oral	Milk	13	9	10	130
	Oral	Ginger ale	22	0	0	90
	Oral	Egg whites ..... 14 Skim milk powder...168 Gm. Karo.....200 cc. Whole milk..... 1.6 liters	315	170	70	1,300
	Intravenous	Amigen..... 2.0 liters	100	100	0	800
Total one day intake			450	280	80	2,620
Severe acute burn	Oral	Glucose in water 20% 1.25 liters	250	0	0	1,000
	Tube	Amigen, oral.....122 Gm. Nutramigen.....340 Gm. Sugar.....244 Gm. Water.....ad 3.7 liters	622	163	63	3,700
	Intravenous	Amigen..... 20 Gm. Glucose..... 75 Gm. Water.....ad 0.5 liter	77	19	0	385
Total one day intake			950	180	63	5,085
Moderate acute burn, preexisting colitis	Oral	House diet	100	50	26	834
	Oral	Glucose in water 10% 3.5 liters	350	0	0	1,400
	Tube	Skim milk powder...150 Gm. Skim milk..... 1.5 liters	135	117	7	1,070
Total one day intake			585	167	33	3,300
Compound fracture of leg, laceration of brain, ruptured kidney	Oral	House diet	115	35	55	1,100
	Oral	Glucose in water 10% 1.4 liters	140	0	0	560
	Oral	Whole eggs..... 7 Skim milk powder..... 75 Gm. Karo..... 90 cc. Chocolate syrup..... 50 cc. Whole milk.....850 cc.	190	100	75	1,840
Total one day intake			445	135	132	3,500

* Amigen (oral), an enzymatic hydrolysate of casein and pancreas.
** Nutramigen contains dextrimaltose, amigen, olive oil, starch, yeast and salts. These products were obtained from the Mead Johnson Company, Evansville, Ind.

65. Davidson and Taylor,[63] Levenson, Green, Lund, Johnson, Davidson and Taylor.[64]

Intubation feeding is important and may be used to increase the intake of food greatly. Medium caliber nasal stomach tubes are used and left in all the time or for many hours a day. If left in continuously, the tube should be removed every third or fourth day for cleaning. About 200 cc. may be given at a time, spaced between meals and at night, but there is a wide variation in the amount and frequency of supplementary tube feedings that different patients will take. It is well to start with half skim milk and half water or with a mixture of protein hydrolysate and carbohydrates. Instead of supplying the mixture in intermittent doses, a drip apparatus may be used which can, after a short period of training, be regulated by some patients themselves. If 125 to 150 Gm. of protein and 2,000 to 2,500 calories are given by intubation in addition to an average house diet, the patient should receive a total of about 200 Gm. of protein with over 4,000 calories. Usually the patients who are given "forced" supplementary feeding will not take the whole of their house diet in addition. It is difficult to get the intake above this level unless intravenous supplements are given. As some patients need 300 Gm. of protein a day, they should be given a diet and have both intubation and intravenous supplements. Sample day's food intakes of some patients are given in the accompanying table. It has been found necessary to vary the method of feeding from case to case and to a lesser extent from day to day.

Patients needing this type of feeding also need more than ordinary doses of vitamins. For two years it has been customary to use vitamin capsules with these diets in order to assure the patients 15,000 units of vitamin A, 1,500 units of vitamin D, 225 mg. of ascorbic acid, 9 mg. of thiamine, 6 mg. of riboflavin and 60 mg. of nicotinic acid. There is evidence that these doses may not always be sufficient.[64] In general, it can be stated that the patient sick enough to need intravenous feeding, alone or as a supplement, for over five days should have supplementary water soluble vitamins given intravenously or intramuscularly in approximately the following daily doses: vitamin C 500-1,000 mg., thiamine 20-40 mg., riboflavin 20-40 mg. and niacin 150-300 mg.

Acute Conditions.—In the presence of actual or threatened surgical shock, the treatment of hypoproteinemia should be by the intravenous route and should consist of human blood, plasma or albumin[66] or a combination of the three. The aim should be to restore the blood volume, red blood cell volume, blood plasma volume and plasma protein level to the point where the circulation is adequate. The best indication of restoration of an adequate circulation is the presence of urine output, normal in amount and of specific gravity between 1.010 and 1.025. At the same time it must not be forgotten that sodium chloride, various vitamins and other substances may be deficient and may need correction. If losses of all these substances continue, allowance must be made for these losses in the amounts given To replace completely the losses of blood or plasma may demand transfusions of whole blood, plasma or both of up to 6 liters in twenty-four hours. However, such amounts must not be given without adequate and frequent clinical and laboratory control, as overtreatment may result in acute pulmonary edema.

As soon as shock or the imminent danger of shock is over, treatment should be shifted to other and less expensive forms of proteins. (The current price to hospitals for dried plasma is about $1 per gram. Albumin is not on the market, but its cost to the public and to the Navy cannot be much less than this if the value of the donated blood and processing costs are both considered.)

Protein feeding should be given intravenously until mouth feeding can be tolerated and should be continued as a supplement until oral feeding, with or without gavage, has been established at a sufficient level not only to maintain the patient in nutritional equilibrium but also to restore at a rapid rate all tissues that have been depleted. Up to 225 Gm. of protein equivalent have been given in twenty-four hours in the form of an acid hydrolysate of casein[67] or an enzymatic hydrolysate of casein and pancreas.[68] The suggestion of Butler and Talbot[69] for increasing the value of intravenous protein hydrolysates by adding glucose to them has been followed successfully. By adding 300 cc. of 50 per cent glucose to 1 liter containing 5 per cent enzymatic hydrolysate and 5 per cent glucose, 1,300 cc. of solution is obtained that is composed of about 4 per cent hydrolysate and 15 per cent glucose. This quantity is given into a large vein with a 20 or 21 gage needle in four hours without much danger of thrombosis of the vein. This mixture may be given three or even four times a day. The speed of administration of this mixture is limited by the glucose present, and the ratio of glucose administration should not exceed 0.8 Gm. per kilogram of body weight per hour. Administration at a faster rate will produce glycosuria and excessive diuresis. Nausea may be caused if the enzymatic hydrolysate is introduced too rapidly, and thrombosis of the vein used for the injection may occur with the acid hydrolysate. Febrile reactions have also been seen occasionally after the use of the enzymatic hydrolysate, but these are usually not serious. A start has also been made to develop solutions of pure amino acids suitable for intravenous feeding.[70] When a high intake of nitrogen in the form of amino acids or digests is furnished during the catabolic period early after injury, the high output of nitrogen may be increased. However, not all the nitrogen administered is lost[71] and patients so treated show very definite evidence of clinical improvement.[72] In cases of serious protein deficiency, this treatment not only will shorten convalescence but will actually save lives.[73] A full presentation of the use of intravenously administered protein digests and amino acids will be made in another paper in this series.

MEDICAL LICENSURE STATISTICS FOR 1944

FORTY-THIRD ANNUAL PRESENTATION OF LICENSURE STATISTICS BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS OF THE AMERICAN MEDICAL ASSOCIATION

Table of Contents

	Page
STATE BOARDS OF MEDICAL EXAMINERS	
Licenses Issued	101
Candidates Examined by Medical Examining Boards	105
Consolidated Examinations	107
Failures	108
Registration by Reciprocity and Endorsement	110
Licentiates Representing Additions to the Medical Profession	113
Licensure Under the Accelerated Program	114
Acceleration of Premedical Courses	115
Required Internships	115
Licensure for the Relocated Physician	116
The Bureau of Information	116
Annual Registration	116
Candidates Examined, 1940-1944	116
Registration, 1904-1944	117
Graduates of Approved Schools and Others Registered, 1922-1944	118
Graduates of Unapproved Medical Schools Registered, 1939-1944	118
Graduates of Schools of Osteopathy Registered by Medical Examining Boards, 1939-1944	119
Physicians Examined on the Basis of Credentials Obtained in Countries Other Than the United States and Canada	122
BOARDS OF EXAMINERS IN THE BASIC SCIENCES	123
NATIONAL BOARD OF MEDICAL EXAMINERS	125
EXAMINING BOARDS IN THE MEDICAL SPECIALTIES	128

Statistical compilations regarding medical licensure are presented annually in the State Board Number of THE JOURNAL. In the following pages will be found the report for the year 1944, which constitutes the forty-third annual presentation. Data are included regarding (*a*) medical examining and licensing boards of the United States, the District of Columbia, the territories and possessions of the United States, (*b*) boards of examiners in the basic sciences, (*c*) the National Board of Medical Examiners and (*d*) examining boards in the medical specialties.

These computations are based on official records received throughout the year from the medical licensing boards of all the states, Alaska, Puerto Rico and the Virgin Islands, the homeopathic licensing boards of Connecticut, Delaware and Louisiana, the eighteen boards of examiners in the basic sciences in operation last year, the fifteen approved examining boards in the medical specialties and the National Board of Medical Examiners. The homeopathic and eclectic examining boards in Arkansas and the homeopathic board in Maryland did not license any one during the year.

The cooperation of the officers of these agencies in furnishing complete reports makes possible these annual compilations. The Council and THE JOURNAL express thanks and appreciation to those who have supplied these data and for other records furnished throughout the year to the office of the Council.

The tables referring to medical licensing boards include figures regarding the number of candidates examined for medical licensure in 1944, the numbers licensed and those who have secured their first medical license and therefore represent additions to the medical profession. The state boards are discussed first, followed by the basic science boards, the National Board of Medical Examiners and the specialty examining boards.

STATE BOARDS OF MEDICAL EXAMINERS

LICENSES ISSUED

All medical and basic science schools in the United States are operating under an accelerated program with the exception of the Woman's Medical College of Pennsylvania, which has an accelerated plan for the juniors and seniors only. The increase in the numbers of annual graduates is reflected in the number of licenses issued to practice medicine. During the year 1944, 9,606 licenses to practice medicine and surgery were issued by the medical examining boards of the forty-eight states, the District of Columbia, Alaska,

TABLE 1.—*Licenses Issued, 1944*

P—Passed; F—Failed.

Puerto Rico and the Virgin Islands, as shown in table 1. Of the 9,606 licenses issued, 7,035 were issued after examination and 2,571 by reciprocity and endorsement of other state licenses or the certificate of the National Board of Medical Examiners.

It does not follow that all physicians certified in a given year after examination were tested in that year. In twenty-three states, the District of Columbia, Alaska, Canal Zone, Hawaii and Puerto Rico the internship is a requisite for practice, but in some of them a physician is permitted to take an examination before completion of the internship and, if successful, the license is withheld until completion of the internship. Licenses are also withheld in some states for proof of citizenship and other technicalities. In others the licenses of those examined in December are dated and issued in the following year. The statistics in table 1, therefore, include many who were examined in 1943 and even a few in previous years. Consequently, figures in this table will not correspond with those hereinafter given, which deal entirely with physicians examined for licensure within the year 1944.

The greatest number of licenses during the calendar year 1944 were issued in California, 912. Three other states licensed more than 700: Pennsylvania 898, Ohio 837 and New York 788. Twenty-two states, the District of Columbia and the territories and possessions licensed fewer than 100. None were licensed by examination in Wyoming. The fewest, 7, were licensed in North Dakota.

While the great majority of physicians was licensed after examination and represents in the main physicians who obtained their medical license on completion of the medical course and before their entr, on active duty with the armed forces, there were 2,571 registered without examination—by reciprocity agreements or by the endorsement of credentials. Seventeen states licensed more physicians by reciprocity or endorsement than by examination. Florida, Idaho, Massachusetts and Rhode Island have no reciprocal agreements, but with the exception of Florida these states endorse diplomates of the National Board of Medical Examiners.

Increases in the number of physicians registered last year as compared with data reported for the year 1943 were noticeable in a number of states and particularly in California, Georgia, Maryland, Michigan, Missouri, Ohio and Pennsylvania. On the other hand, decreases were significant in some states. These variances are attributable to some extent to the accelerated program of the medical schools and the graduation of two classes of students by some schools in one year. In New York there was again a reduction in foreign graduates examined for licensure.

Thirty were registered in the territories and possessions as follows: by examination Alaska 3 and Puerto Rico 18; by endorsement Alaska 3, Puerto Rico 2 and the Virgin Islands 4.

Totals for nine previous years and for 1944 by all methods of licensure are shown for comparison in table 3. The high figures for the years from 1936 to 1941 in the annual number of licenses issued were due to the licensure of foreign graduates. In 1944 there was an increase of 1,211 over the number registered in the previous year. Acceleration started in most medical schools in the United States on July 1, 1942.

The total graduates for the four-session three-year cycle to July 1, 1945 is estimated at 20,201. For the three years 1942, 1943 and 1944, 26,611 physicians received licenses. While this figure includes physicians previously licensed who are migrating to other states, it is believed that by the completion of the accelerated medical school cycle in June 1945 the great majority of recent graduates probably will have been licensed prior to entry on active duty with the armed forces.

TABLE 3.—*Licenses Issued, 1935-1944*

	Examination	Reciprocity and Endorsement	Total
1935	5,725	2,194	7,919
1936	6,275	2,772	9,047
1937	6,629	3,204	9,833
1938	6,557	2,956	9,513
1939	6,400	2,872	9,272
1940	6,289	2,866	9,155
1941	6,053	2,759	8,812
1942	6,141	2,469	8,610
1943	6,059	2,336	8,395
1944	7,035	2,571	9,606
Totals	63,163	26,999	90,162

In the past ten year period 90,162 medical licenses have been issued, 63,163 after examination and 26,999 by endorsement of credentials.

The figures given do not altogether represent individuals but include persons who may have been licensed in more than one state during a given year; nor does the total represent additions to the medical profession, since a physician may be licensed by examination in a nonreciprocating state. Among those licensed by reciprocity or endorsement are some who received licenses by endorsement of the certificate of the National Board of Medical Examiners but may not have been previously licensed. In tables 11, 12 and 13 can be noted the number who secured licenses for the first time and represent additions to the medical profession in the United States and its territories and possessions.

CANDIDATES EXAMINED BY MEDICAL EXAMINING BOARDS

In table 2 are recorded figures referring to those examined for medical licensure by individual states, the District of Columbia, Alaska and Puerto Rico, indicating the numbers who passed and failed in each state and the medical school of graduation. Throughout the year 6,791 were examined, of whom 5,985 passed and 806 failed. Candidates represented sixty-nine approved medical schools in the United States, nine approved medical schools of Canada, ninety-two faculties of medicine and two licensing corporations of other countries, seven medical schools now extinct, six unapproved institutions and seven colleges of osteopathy and 1 individual who had not completed the medical course. Osteopaths who were granted the privilege to practice medicine, surgery or both by the medical examining boards are included in these statistics. Osteopaths in other states who obtain the legal right to special practice by the osteopathic board are excluded from these compilations.

Examination schedules have been adjusted to coincide as nearly as possible with the graduating dates of the medical schools located within their states. Executive officers and members of examining boards are to be commended for adding this work to their already overtaxed responsibilities.

The 6,791 examinees represented 5,432 graduates of approved medical schools in the United States, of whom 2.9 per cent failed; 61 graduates of approved Canadian schools, 27.9 per cent failures; 25 who graduated from approved medical schools no longer operating with 8.0 per cent failures; 691 graduates of faculties of medicine located in countries other than the United States and Canada, 53.0 per cent of whom failed, and 582 graduates of unapproved institutions with 45.4 per cent failures. The number of examinees in each of these categories was considerably less in 1944 than in the previous year. In 1944 there were 1,002 fewer examinees among graduates of approved medical schools, 10 fewer Canadian graduates, 76 fewer graduates of schools now extinct, 340 fewer graduates of foreign faculties of medicine and 175 fewer from unapproved institutions. This decrease may be ascribed primarily to the accelerated program and the graduation of two classes by medical schools in 1943, by most approved institutions. Most of these graduates were examined in the year of graduation and appear in the statistics on candidates examined as published in the 1944 State Board Number. However, large numbers of those examined late in 1943 were not actually licensed until 1944. Such physicians were mainly responsible for the 1944 increase in licenses issued, discussed earlier in connection with table 1.

TABLE 4.—*Graduates of Medical Schools in Canada Examined for Licensure in the United States, 1944*

	Examined	Passed	Failed

West Virginia	1	1	0
Totals	61	44	17

The closing of Rush Medical College several years ago necessitated the placing of graduates of this school among the extinct medical schools. The majority of physicians recorded in the classification of extinct medical schools were graduates of Rush. In 1944 there were far fewer graduates of this school examined than in 1943. For several years the number of graduates of foreign faculties of medicine has been decreasing. Table 27, page 122, contains totals for this category of examinees from 1930 to 1944. There were 175 fewer graduates of unapproved institutions examined. Considerable reductions occurred in Massachusetts and Ohio.

This decrease is not seen in the tables showing licenses issued in 1944 because the licenses of many who were examined in 1943 were issued and dated in 1944, since many schools graduated their second class of 1943 late in the year.

As in table 1, the 6,791 physicians and others examined for medical licensure do not represent an equal number of individuals, since a candidate might take an examination in more than one state and is counted in each state. However, if a candidate fails more than once in a given state within the year he is counted in that state as only one failure.

The greatest number of graduates of any one school examined was 247 representing Jefferson Medical College. This school had one graduating class in 1943 and two in 1944, in January and September. Licenses were earned by these persons in twenty-one states. Five of the examinees failed. More than 200 graduates of two other schools applied for licenses by examination last year, namely Tulane University 213 and the University of Pennsylvania 217. These high figures also represent two graduating classes. However, a small percentage are graduates of other years. Figures published in 1943 [1] revealed that in the year 1942 there were examined 4,609 graduates of 1940, 1941 and 1942 from approved medical schools in the United States. In that year the total number of graduates examined from sixty-five approved medical schools in the United States was 4,905. The percentage of failures of recent graduates in 1942 was 1.9 and of all graduates of these schools 2.4. In the calendar year 1944, while no compilation of recent graduates has been made, 2.9 per cent of the 5,432 graduates of the approved medical schools in the United States failed.

Twenty-three approved schools in the United States had no failures before medical licensing boards, thirty-two less than 5 per cent and six between 5 and 10 per cent. There were eight schools with 10 per cent or more failures in state examinations. These figures and percentages are modified by data on those who were examined by the National Board of Medical Examiners in its final examination as well as those passing state tests (see table 6).

Nineteen graduates of the newly developed four year medical school at the University of Utah School of Medicine, which graduated its first class in 1944, were tested for medical licensure in the state of Utah, and all were successful. This school was formerly a school of the basic medical sciences. It earned approval as a four year medical school by the Council on Medical Education and Hospitals in 1944.

Graduates of Northwestern University and the University of Pennsylvania were examined in the greatest number of states—twenty-six. Harvard and Jefferson alumni were tested in twenty-one states. All other schools had their graduates examined in fewer than twenty states. The medical schools of Indiana, Boston University, Albany, Bowman Gray, Southwestern, Texas, Utah and Vermont had graduates examined in fewer than four states. Only 3 graduates of Boston University and Albany Medical College took a state written examination.

TABLE 5.—*Source of Candidates Examined, 1944*

Medical Schools	Number of Schools	Number Examined	Number Passed	Number Failed	Percentage Failed
Approved, in United States	69	5,432	5,275	157	2.9
Approved, in Canada	9	61	44	17	27.9
Extinct	7	25	23	2	8.0
Foreign	94	691	325	366	53.0
Unapproved Schools	13	582	318	264	45.4
Totals	192	6,791	5,985	806	11.9

Graduates of the Southwestern Medical College appeared for the first time in medical licensure statistics. This new school was developed at Dallas, Texas, in 1943 and has to date had two graduating classes, in March and December 1944. There were 118 graduates tested in two states (Mississippi 1 and Texas 117)

1. J. A. M. A. 122:95 (May 8) 1943.

with no failures. This medical school is approved by the Council on Medical Education and Hospitals.

Three of the five homeopathic boards in existence examined 7 candidates: Connecticut 3, Delaware 3 and Louisiana 1. The homeopathic boards in Arkansas and Maryland did not examine any one in 1944. The one eclectic board in existence in Arkansas likewise did not examine a candidate.

Sixty-one graduates of nine approved medical schools in Canada applied for medical registration in eighteen states (table 4), of whom 44 passed and 17 failed. The greatest numbers represented McGill University (21) and the University of Toronto (14). Graduates of each of those two schools were examined in eight states. Normally larger numbers of graduates of these schools secure licensure in this country. In 1942 the figures were 60 for McGill and 45 for Toronto.[2] In 1943 they decreased to 23 and 19 respectively. This reduction in graduates from McGill and Toronto seeking licensure in the United States is probably related to the war.

Three Canadian schools had no failures before United States licensing boards, while the other six schools had percentages higher than 14. The highest percentage of failures was 66.7, from 9 graduates of the University of Montreal examined in six states. The state of New York examined 17 Canadian graduates and California 11. All other states examined fewer than 6.

The 582 graduates of unapproved and osteopathic schools represented 346 graduates of unapproved medical schools, of whom 153 passed and 193 (55.8 per cent) failed, and 236 graduates of schools of osteopathy, of whom 165 passed and 71 (30.1 per cent) failed. Included among unapproved graduates is 1 candidate who had not completed the medical course. He was passed in Mississippi.

Graduates of osteopathic schools were examined by the medical boards of eleven states, namely Colorado, Connecticut, Delaware, Indiana, Massachusetts, Nebraska, New Hampshire, New Jersey, Ohio, Oregon and Texas, while graduates of unapproved medical schools were examined in three states—Illinois, Massachusetts and Virginia.

Graduates of medical schools of other countries were examined in twenty-one states and Puerto Rico.

The source of candidates for licensure last year on the basis of examination is further analyzed in table 5, giving totals for five groups, namely approved medical schools in the United States and those from Canada, schools no longer in existence, schools of foreign countries and unapproved schools. As already mentioned, from the United States schools 2.9 per cent failed as did 27.9 per cent of the graduates of Canadian schools. The greatest percentage of failures represented two groups, foreign schools and unapproved schools. In these two groups, 53.0 and 45.4 per cent respectively failed. From the extinct medical schools 8.0 per cent failed.

Elsewhere (see table 11, page 113) are given figures referring to actual licentiates and additions to the medical profession.

CONSOLIDATED EXAMINATIONS

In the calendar year 1944, 5,432 graduates of approved medical schools in the United States were examined by medical licensing boards, of whom 2.9 per cent failed (table 6). In the same period 1,135 graduates of approved medical schools in the United States

2. J. A. M. A. 122:93 (May 8) 1943.

were tested in part III of the examination of the National Board of Medical Examiners, of whom 1.8 per cent failed. A comparison of the failures in each group revealed that in some instances schools having a high percentage of failures before licensing boards had few, if any, failures before the National Board of Medical Examiners. In these consolidated figures for 6,567 graduates, the percentage of failures of approved medical schools in the United States was 2.7.

Of the Canadian graduates, 27.9 per cent failed state board tests and 23.9 per cent the combined tests. Ten graduates of three Canadian schools were examined by the National Board of Medical Examiners and all passed. Only 20 graduates of foreign faculties of medicine were admitted to the National Board's final examination while 691 were examined by state licensing boards. The National Board of Medical Examiners does not admit to its examinations the graduates of unapproved medical schools in the United States.

The total of all examined before medical licensing boards was 6,791, of whom 5,985 passed and 806, 11.9 per cent, failed. For both groups—state boards and the National Board—7,957 were examined; 7,130 passed and 827, or 10.4 per cent, failed. Fifty-two existing and one extinct approved medical school in the United States were represented in the National Board's examinations. Twelve of these schools had graduates examined in each group with no failures in either. These schools were Colorado, George Washington, Northwestern, Chicago, Louisville, Boston, Washington, Columbia, Bowman Gray, Meharry, Baylor and Vermont.

Four schools had failures above 10 per cent in the combined statistics: Georgetown 16.4 per cent, Howard 15.8 per cent, Creighton 12.2 per cent and Loyola 11.1 per cent.

FAILURES

Data recorded in table 7 refer to failures before medical licensing boards by licentiates of 1944. In presenting these statistics the United States is divided into two groups—the thirty-one states in which approved four year medical schools are located and those, including Alaska and Puerto Rico, which have no approved medical school within their boundaries. Included is the number who failed state board examinations and were graduates of a medical school located in the state in which they were examined and, for comparison, the number of graduates licensed in a given state who obtained their professional training in schools in other states.

Two of the three approved medical schools of Massachusetts had only one failure last year in the state, while 25.4 per cent of those who obtained their medical education in thirty-four other approved schools failed. In New York 2.8 per cent of those who studied medicine in eight of the nine schools located in that state who appeared for licensure in 1944 had previously failed, and 23.4 per cent who obtained their medical training in thirty-six schools located in other states failed. Sixty-five physicians failed examinations in the state in which the medical school they attended was located, and nineteen states had no failures from schools within their boundaries. In no instance was the percentage of failures greater in the case of graduates of schools located within the state of licensure.

Practically all states require the applicant to receive a general average of 75 per cent and 50 per cent in any one subject. In case of failure in not more than two subjects the applicant is entitled to another examination in those subjects within twelve months. A few states consider such individuals as conditioned in the subjects in which they fail and do not report them to the Council as failures. In these instances they are not considered in the calculations in this study. When their grades are raised after a successful test in the subjects in which they failed they are recorded among those who passed.

In eighteen states having no medical school only three reported failures, namely Florida, New Hampshire and Rhode Island. Fifty-one schools were represented at Florida examinations with 6.2 per cent failures. In New Hampshire with five schools represented 16.7 per cent failed, while in Rhode Island nine schools were represented with 14.3 per cent failures.

The total number examined in the first group—states in which approved four year medical schools are located—was 4,978, while in the second group—states which have no approved medical school within their boundaries—454 were examined.

In another table dealing exclusively with failures (table 8) the data are further subdivided by the number of candidates who were licensed after previous failure. The figures are presented for three groups,

namely graduates of approved medical schools, foreign faculties of medicine and unapproved institutions. These groups are classified according to the number licensed after failing a state board examination once and after two or more failures and indicates whether the single failures have been in the state of licensure or elsewhere; the table also indicates whether multiple failures have been in the state where licensed and/or elsewhere. The total number of candidates examined and licensed, or granted licenses without written examination—by reciprocity or endorsement—in each state, and the total number of failures in all groups is shown.

In the computation of these statistics it was noted that 58 graduates of foreign faculties of medicine failed five or more times before licensure, likewise 4 graduates of unapproved institutions failed at least five times. A graduate of one approved school made 7 unsuccessful attempts before obtaining licensure. Of the foreign graduates 16 had five failures before obtaining a license, 14 failed six examinations, 6 failed seven, 8 eight, 6 nine, 3 ten, 1 each eleven and twelve, 2 thirteen and 1 failed eighteen tests.

Totals	9,606	44	29	10	6	3	47	16	124	37	35	36	1	28	6	1	423

Of the 9,606 licensed in 1944, 423 had previously been unsuccessful before a licensing board. From the approved schools, 92 of those licensed had previously failed a state board examination. Forty-four failed once before being licensed in a given state and 29 after one failure elsewhere. Nineteen received licenses after more than one failure, 10 of whom were registered in the original state, 6 elsewhere; 3 failed in the state where licensed and elsewhere.

The graduates of foreign faculties of medicine who were registered after previous failures numbered 259 and those of unapproved schools 72.

The 4 graduates of unapproved institutions failed as follows: five tests, 2; six tests, 1; and 1 of the graduates failed eleven attempts. The majority of these physicians with multiple failures were Massachusetts and New York examinees.

In twenty-one states all physicians licensed last year had no failure in a state medical examination before being registered. There were 2,461 such individuals. With the exception of California, Illinois, Massachusetts, New Jersey, New York and Ohio the number of physicians licensed throughout the country in each state after previously having failed was less than 10.

REGISTRATION BY RECIPROCITY AND ENDORSEMENT

A summary of the reciprocity and endorsement policies of the various states, the District of Columbia, Alaska, Hawaii and Puerto Rico will be found in table 9. Four states—Florida, Idaho, Massachusetts and Rhode Island, as well as Hawaii—have not established reciprocal agreements with regard to medical licensure. Of these four all except Florida will register diplomates of the National Board of Medical Examiners by endorsement, as will also Hawaii. Those desiring licenses by reciprocity or endorsement in seventeen states and the District of Columbia are required to obtain a certificate from the state board of examiners in the basic sciences before being eligible for licensure.

Reciprocal relationships in medical licensure have been established in forty-four states, the District of Columbia, Alaska and Puerto Rico. Twenty-five of these states, Alaska and Puerto Rico reciprocate with specifically indicated states. Twenty-five states, including six which have specific reciprocity agreements, are given discretionary powers under the medical practice act. These states will register physicians who present

This summary should be supplemented by direct communication with the

Some states have additional requirements for graduates of schools outside the United States and Canada.

+, indicates reciprocal or endorsement relationships have been established; .. indicates no reciprocal or endorsement relationships have been established. (See column—"At the discretion of the board").

1. 1st P, first papers required; ⊕, in citizenship column indicates full citizenship required.
2. In most cases there is a small additional recording or registration fee.
3. If state of original license grants similar privileges.
4. Internship accepted in lieu of one year's practice.
5. Professional practice required.
6. No professional practice required.
7. Just preceding application.
8. No basic science reciprocity—examination must be within the state.
9. Basic science certificate required either by reciprocity or examination in addition to basic science subjects of National Board.
10. Reserve officers not eligible.
11. Leading medical schools of Great Britain recognized.
12. Oral examination required when original license is ten or more years old.
13. Applicant must have resided in the state used as basis or application for one year after date on said certificate.
14. Oral examination required.
15. Unless in practice in another state for five years.
16. Actual practice for a period of three years immediately preceding date of application.
17. Practical, clinical examination required.
18. Foreign graduates only.
19. Regular and Homeopathic boards.
20. Licentiates of Florida, Idaho, Massachusetts, Rhode Island and Hawaii not eligible for license by reciprocity.
21. Regular board.
22. Fee same as applicant's state charges if more than $50.
23. Oral examination required if applicant's state requires it.
24. If an applicant passes the examination in the state from which he transfers after the completion of his internship, no practice is required.

credentials which correspond with those required by their respective states at the time such licenses were issued. The states in which diplomates of the National Board of Medical Examiners and medical officers of the government services are accepted for licensure on the basis of these credentials are also indicated.

citizenship requirement. This is indicated in footnotes. Few states will accept graduates of foreign faculties of medicine on a reciprocal basis. Additional requisites or exemptions are included in footnotes.

This chart will be available in reprint form. It has proved to be of material assistance to those physi-

secretary of the licensing board of the state in which the physician is interested.

25. Internship accepted if served in this state.
26. Internship accepted—considered equivalent to two years' practice.
27. Fee $25.
28. Conditionally.
29. A two year internship is accepted.
30. Diplomates of National Board not required to have been in practice for three years.
31. Graduates before 1907 required to take oral examination.
32. Clinical examination required.
33. Reciprocity applicants only.
34. Supplemental examination required in certain cases when accepting the examination of a state with whom reciprocal relations have not been established.
35. May be licensed after a special (written) supplemental examination.
36. Fee for license on basis of National Board certificate, $50.
37. For matriculants after Oct. 15, 1937.
38. Fee, $20.
39. While on active duty only.
40. Permanent license withheld until completion of citizenship.
41. Graduates of foreign medical schools effective Sept. 15, 1935. Canadian schools exempted effective Sept. 19, 1939.
42. Graduates of foreign medical school are not accepted.
43. Graduates of foreign medical schools must have fulfilled all requirements of California prior to admittance to examination for any certificate used as basis of application to California.
44. Graduates of approved schools of Canada eligible.
45. Not applicable to citizens of Canada.
46. Canadian citizens are required to file first papers.
47. Fee, $15.
48. Same as required of Utah candidates applying for licensure.
49. Diplomates are accepted on basis of reexamination. The question and answer manuscripts from the National Board are submitted for regrading.
50. All applicants must be graduates of a medical school approved by the American Medical Association.

Specific requirements, such as professional practice, oral examination and internship, are recorded, as is also the fee for a license without written examination. Citizenship prequisites are mentioned. In some states physicians of Canadian birth are exempt from the

cians who are contemplating locating in another state.

The facts recorded in this table are intended to be merely general statements of licensure policies. A physician using this chart for reciprocity purposes should supplement the information contained therein by direct

communication with the secretary of the licensing board of the state in which he is interested.

The credentials presented by physicians granted licenses in 1944 to practice medicine and surgery without written examination are given in table 10. There were 2,547 so registered on the basis of licenses issued by other states, the District of Columbia, the territories or possessions or foreign countries, the certificate of the National Board of Medical Examiners or one of the government services.

The greatest number of licenses issued by this method in any one state were 469 in California. New York issued 335. Four other states endorsed 100 or more, namely Ohio 106, Michigan 146, New Jersey 159 and Texas 160. The largest group representing the same type of credentials were the 702 diplomates of the National Board of Medical Examiners. On the basis of this certificate 259 were certified in New York. One hundred or more physicians presented licenses issued in Illinois, Missouri, New York, Ohio, Pennsylvania and Tennessee. No physician holding a Nevada or New Mexico certificate applied for registration in another state during the year. In Arizona and in New York one physician was registered on the basis of foreign credentials, presenting licenses from Great Britain and Austria respectively.

Four were admitted to private practice in the Virgin Islands on presentation of satisfactory credentials. Thirteen medical officers of one of the government services received licenses without written examination in four states: California 8, Kentucky 1, Texas 3 and Utah 1.

Two physicians from Alaska were registered in California and one physician presented for endorsement in New York a license obtained in Puerto Rico. The New York Board of Medical Examiners accepted the diploma of a foreign physician in lieu of a licensure credential.

Not included in the table are 24 osteopaths licensed by medical examining boards in seven states. They are omitted from this compilation since the credentials presented were osteopathic licenses. These individuals secured licenses in Indiana 3, New Hampshire 2, Ohio 3, Oregon 8, Texas 1, Wisconsin 5 and Wyoming 2.

Seventy-five licentiates of New York secured licenses to practice in New Jersey, while 61 from New York and 76 from Illinois were registered in California.

Diplomates of the National Board of Medical Examiners were registered on the basis of this credential by forty licensing boards last year. There were 702 individuals who presented these credentials. The greatest number accepted by any one state was in New York, where 259 secured licenses to practice medicine. Of all who were registered by reciprocity and endorsement, over one fourth presented National Board credentials.

The numbers of physicians securing licenses by reciprocity or by endorsement has increased in the last three years. The figure for 1944 (2,547) represented 272 more licenses issued than in 1943.

LICENTIATES REPRESENTING ADDITIONS TO THE MEDICAL PROFESSION

The number of physicians who received their first license to practice medicine and surgery in 1944, and therefore represent additions to the medical profession, are recorded in table 11. Figures represent candidates examined in 1944 and immediately licensed, also those examined in previous years whose licenses were withheld for lack of internship, citizenship and other technicalities and issued in 1944, and those without a state license who were during the year certified on the basis of the examination of the National Board of Medical Examiners, government services, Canadian and foreign credentials. The majority represent recent graduates. However, the majority of the recent graduates are now in the military services and only a small percentage of them can be considered to be additions to the present civilian physician population. It is not known how many of these are in civilian practice.

There were 6,933 additions to the medical profession in 1944. The number removed by death in the same

period was 3,627. It would appear, therefore, that the physician population in the United States last year was increased by 3,306. Many more than this latter number were added to the armed forces as medical officers in 1944, so that there has resulted an actual decrease in physicians available to civilians in the course of the year. In view of the accelerated program, one might expect that additions to the profession would be considerably higher. While two classes were graduated from most medical schools in 1943, the number of physicians added to the profession in that year did not increase, since many physicians who obtained M.D. degrees in December of that year were not able to receive licenses until early in the year 1944, owing to administrative details. In 1944 the number in this group was 979 more than in the previous year.

The greatest number of physicians in any one state, 821, was added to the profession in Pennsylvania. Both New York and Ohio added more than 600, and California and Missouri more than 300. By comparison

with 1943 figures[3] it can be noted that considerably more were licensed and represent additions to the profession in 1944 in the cases of Colorado, Georgia, Kansas, Kentucky, Maryland, Michigan, Missouri, Nebraska, Ohio and Pennsylvania. Most significant increases occurred in Ohio and in Pennsylvania, where the increases totaled 474 and 377 respectively.

No one was added to the profession in Nevada. New Mexico or Wyoming, while in seventeen states between 100 and 299 received initial licenses. Twenty-four states, the District of Columbia, Alaska, Virgin Islands and Puerto Rico added fewer than 100.

Of the 6,933 licentiates constituting additions to the medical profession last year, 6,469 secured their licenses by examination and 464 by endorsement of credentials. The latter represent in the main diplomates of the National Board of Medical Examiners.

Table 12 records increases in the physician population grouped in nine geographic divisions. The Middle Atlantic, East North Central and West North Central group of states added the greatest number, over 1,000 each. More than 500 were added in two groups—the South Atlantic and West South Central states. The fewest number of physicians, 146, were added to the medical profession in the Mountain states. Three states in this group—Nevada, New Mexico and Wyoming—did not add a single physician to the medical profession last year.

Comparative figures for nine years and 1944 are given in table 13. Last year the number of physicians representing additions to the medical profession

TABLE 13.—*Licentiates Representing Additions to the Medical Profession, 1935-1944*

Year	Examination	Reciprocity and Endorsement	Total
1935	5,099	411	5,510
1936	5,548	629	6,177

1944	6,469	464	6,933
Totals	56,082	4,831	60,913

increased 979 over the previous year. In the ten year period the greatest number of physicians were added to the medical profession in 1944.

In ten years there were 60,913 physicians added to the profession; 56,082 were licensed after a successful written examination and 4,831 by reciprocity and endorsement. In the same period 90,162 licenses were issued, 63,163 by examination and 26,999 by endorsement of credentials. Thus 29,249 licenses were obtained by physicians who had previously been licensed to practice medicine.

Estimated figures indicate that on Jan. 1, 1945 the number of physicians in continental United States including those licensed in 1944 was 191,689. Excluding physicians who are in military service, engaged in full time hospital work, retired, engaged in full time teaching or not in practice, there remain approximately 100,000 physicians in private practice, some of whom are part time teachers.

LICENSURE UNDER THE ACCELERATED PROGRAM

All states in the Union, as well as the District of Columbia, Alaska, Hawaii and Puerto Rico, have made certain adjustments in their licensure legislation or practices, where such were required, to facilitate the licensure of graduates under the accelerated program. Legislation in four states (District of Columbia, Georgia, Illinois and Minnesota) is such as might not provide for students who have completed all of their

3. J. A. M. A. 125: 133 (May 13) 1944.

medical school work under the accelerated program and spend a week or two less than thirty-six months in medical school. Such students are typical throughout the country because those starting school July 1, 1942, for example, are likely to graduate a week or so prior to July 1, 1945.

ACCELERATION OF PREMEDICAL COURSES

The minimum requirement of the Council on Medical Education and Hospitals for admission to approved medical schools since 1918 has been two years of college training, and in 1938 three years was recommended. With the exception of California, Connecticut and Nebraska (table 14) the state licensing boards, by statute in the majority of instances, require that an applicant for licensure must present evidence of having completed two years of college. In November 1942 the Council on Medical Education and Hospitals recommended that for the duration of the war premedical education, including satisfactory courses in physics, biology and inorganic and organic chemistry, be included within two calendar years. Such a program was adopted by practically all medical schools of the country.

The Army Specialized Training and Navy V-12 premedical programs call for less than two years of college

training, but in both of these programs the studies are continuous and provide for the student carrying more than the normal peacetime studies per semester. Both the Army and Navy programs provide for work well in excess of the sixty semester hours constituting the normal two academic years of medical study. The information received from those states whose licensure laws include specific premedical requirements seems to indicate that there should be no licensure difficulties encountered by students whose premedical work was taken under the Army Specialized Training or Navy V-12 or comparably accelerated civilian programs.

REQUIRED INTERNSHIPS

In tables 15 and 16 are listed the medical schools and licensing boards now requiring internships for the M.D. degree and licensure respectively. Six schools in the United States and 4 in Canada require an internship for graduation. Although relatively few schools require the internship for the M.D. degree, this is a requirement for licensure by twenty-three state medical licensing boards, the Arkansas and Connecticut homeopathic medical examining boards, the District of Columbia, Alaska, Canal Zone, Hawaii and Puerto Rico. Table 17 lists these states and indicates the relationship of this requirement to the nine month internship. Eleven states, the Connecticut homeopathic examining board, Alaska, the Canal Zone and Puerto Rico will accept a nine month internship as fulfilling the internship requirement. Ten states and the District of Columbia require an additional three months in a civilian hospital or military service but will permit applicants for licensure to write the examination on completion of the nine month internship but will withhold the license until this is completed. In two states physicians are not eligible to take the examination until after completion of a year's internship, three months of which may be in the military service. This is true

TABLE 16.—*Internship Required by Medical Licensing Boards of All Candidates*

Alabama	Iowa	Pennsylvania
Alaska	Michigan	Puerto Rico
Arkansas (homeo. board)	Montana	Rhode Island
Canal Zone	Nevada	South Dakota
Connecticut (homeo. board)	New Hampshire	Utah
Delaware	New Jersey	Vermont
District of Columbia	New Mexico	Washington
Hawaii	North Dakota	West Virginia
Idaho	Oklahoma	Wisconsin
Illinois	Oregon	Wyoming

Some states require the internship of graduates of medical faculties abroad and of reciprocity or endorsement applicants.

Illinois, Michigan, North Dakota, Pennsylvania and Washington require the internship to be a rotating service, while New Jersey recommends this type of service.

TABLE 17.—*Nine Month Internship*

	Additional Three Months in Civilian Hospital or Military Service Required	
Accepted as Fulfilling Internship Requirement	Will Give Examination at End of Nine Months	Will Not Give Examination Until Completion of Year's Service
Alaska	Alabama [1]	Arkansas (homeo. board)
Canal Zone	Dist. of Columbia [1]	Illinois [2]
Connecticut (homeo. board)	New Jersey [1]	New Mexico
Delaware	North Dakota

1. Will also give examination on completion of the medical course but without license until internship is completed.

2. Military medical service must be in a military hospital.

Some states require the internship of graduates of medical faculties abroad and reciprocity or endorsement applicants.

Hawaii which requires an internship for licensure has not reported on the relationship of this requirement to the shortened internship.

Illinois, Michigan, North Dakota, Pennsylvania and Washington require the internship to be a rotating service, while New Jersey recommends this type of service.

also of the homeopathic examining board in Arkansas. Officers seeking licenses in these three states must delay licensure until after the war or seek furloughs to take the examinations. In the past it has been possible for officers to obtain furloughs for this purpose.

Five states (Connecticut, Maryland, Missouri, Texas and Virginia) whose laws do not require an internship withhold the licenses of candidates from schools requiring an internship for the M.D. degree until the internship is completed. In these states the examination may be taken at any time after completion of the medical school course.

The licensing boards of Illinois, Michigan, North Dakota, Pennsylvania and Washington require the internship to be a rotating service, while New Jersey recommends this type of service.

A few of the medical schools and licensing boards maintain their own list of hospitals acceptable for intern training, but the list of approved internships compiled by the Council on Medical Education and Hospitals is generally used.

LICENSURE FOR THE RELOCATED PHYSICIAN

To assist the physician returning to civilian practice or in locating in areas where there are shortages of physicians, the licensing boards of nineteen states, Alaska and Puerto Rico provide for the issuance of temporary permits, usually without immediate examination. These states, the length of the validity of the permit and the number of permits granted during the last calendar year are shown in table 18. During the past year four additional states and Alaska and Puerto Rico have provided for the issuing of temporary permits. Others are considering adjustments, probably impelled in part by the recent recommendation of the Procurement and Assignment Service that such legislation be enacted by states to facilitate the relocation of physicians into needy areas, especially in the case of discharged medical officers desiring such relocation.

In addition, the New Jersey medical practice act exempts from its requirements a lawfully qualified physician and surgeon of another state taking charge temporarily of the practice of a lawfully qualified physician of New Jersey during his absence from the state. Such permission may be granted by the board of medical examiners for a period of not less than two weeks nor more than four months but not to exceed one year in the aggregate.

THE BUREAU OF INFORMATION

Among its other responsibilities, the Bureau of Information of the American Medical Association is helping veteran medical officers with their medical practice and relocation problems. This is done through close association with state and county medical societies as an entirely voluntary effort without any attempt to direct the location of a physician.

An officer can obtain a brief but comprehensive picture of the economic status of any particular area he is interested in from the data contained on county summary sheets. This includes data on population, principal cities, physicians, hospital and medical facilities and pertinent economic, social and financial information. A copy of this summary sheet is forwarded to the inquirer and a copy of the letter to him is sent to the state and county medical society concerned.

In addition to the information contained on the summary sheets, other data are available for interested officers. Requests for full or part time salaried medical positions from industries, institutions and other organizations, requests from practicing physicians for associates, needs for specialists and requests of individuals for practices are cross filed and kept current by a return post card system which keeps the Bureau of Information informed of final locations, filling of vacancies and the securing of physicians.

An active cooperative effort of state and county medical societies in furnishing the Bureau of Information with current, up to date information about needs for doctors will enable the American Medical Association to be of definite help to veteran medical officers.

ANNUAL REGISTRATION

Twenty-seven states, the District of Columbia, Alaska and Hawaii require physicians to register their license annually. In table 19 are listed the states which exact this requirement. Some of these states require such registration whether or not physicians reside in the state. The fee is generally $2. With two exceptions, Colorado and Hawaii, the requirement has been waived for physicians in military service. In some instances legislative action was necessary to obtain a waiver.

CANDIDATES EXAMINED, 1940-1944

In table 20 are tabulated the number of candidates examined for medical licensure in the United States and its territories and possessions for the five year period from 1940 to 1944. For each year there is recorded the number who passed and failed licensing examinations. Totals for the five year period and the percentage of candidates who failed also are given.

During this period 37,878 examinations were given; 31,935 were successful and 5,943, 15.7 per cent, failed. New York leads in the number of examinations given. In this state in the five year period there were 4,002 successful tests. Other states passing more than 2,000

TABLE 19.—*Annual Registration*

* Biennial registration.

included Pennsylvania 2,708, California 2,220 and Illinois 2,046. More than 1,000 were examined in seven other states and passed, namely Massachusetts, Michigan, Minnesota, Missouri, Ohio, Tennessee and Texas. The greatest percentage of failures, 55.6, occurred in Massachusetts. The high percentage in this state is due to the fact that, by law, the licensing board admitted to its examinations the graduates of unapproved medical schools and graduates of schools of osteopathy, many of whom repeatedly fail. New York had a failure percentage of 46.8, occasioned in large part by the admittance to examination of a considerable number of graduates of foreign faculties of medicine, who likewise repeatedly fail. Other high percentages of failures occurred in Connecticut, Maine, Nevada, New Hampshire and New Mexico. On the other hand, thirty-four states failed less than 5 per cent in the five year period. These included nine states which had no failures: Arkansas, Delaware, Indiana, Kansas, North Carolina, Oklahoma, South Dakota, Utah and West Virginia.

The percentage of failures in all states has decreased from 20.6 in 1940 to 11.9 in 1944. The lowest percentage of failures in this five year period occurred in 1943, when 10.9 per cent failed.

These figures represent examinations given and not individuals. A candidate who fails more than once in a state in a given year is counted only once, but should he also fail in a succeeding year he is counted in that year also. The same is true of successful candidates who migrate to other states. This group represents a recapitulation of the statistics computed annually and assembled for comparative purposes. It gives only a fair approximation of the number of physicians added to the profession in five years by the written examination method. Table 13, page 114, gives the corrected compilation of the number of physicians representing additions to the medical profession for this period.

REGISTRATION, 1904-1944

A study of totals and percentages for forty-one years (1904-1944) is included in table 21. This tabulation covers physicians registered by written examination and by reciprocity or endorsement of credentials. There is no definite trend in the numbers annually registered from 1904 to 1933, although in 1918 the number registered dropped to the all time low record of 4,231. After 1933 there was an upward trend for a time followed by a decline which terminated in 1942. The decrease of more than 1,200 in 1918 was due to the sudden withdrawal of physicians and recent graduates from civilian life during World War I. By contrast, in 1943 the number registered increased almost 1,300 over the preceding year. The increase is a result of the accelerated curriculum and the graduation of two classes by many medical schools in that year. Under the accelerated curriculum the majority of medical schools had one graduating class in 1944, which accounts for the decrease in the numbers examined. Unless appropriate measures are adopted at once, there will be a sharp decline in graduates and licenses issued commencing in 1948. Even if such adjustments are made now there will be a decline in graduates, because inadequate numbers of qualified students are now permitted to engage in premedical studies.

TABLE 21.—*Registration, 1904–1944*

Year	Examined	Passed	Per-centage Failed	Reciprocity or Endorse-ment	Total Regis tered
1904	7,056	5,693	19.3	1,005	6,698

1934	6,144	5,627	8.4	2,160	7,788
1935	6,443	5,859	9.1	2,196	8,055
1936	6,917	6,223	10.0	2,775	8,998
1937	7,334	6,604	10.0	3,203	9,807
1938	7,461	6,589	11.7	2,956	9,545
1939	7,754	6,493	16.3	2,872	9,365
1940	7,925	6,290	20.7	2,865	9,155
1941	7,539	6,057	19.7	2,758	8,815
1942	7,221	6,118	15.4	2,469	8,587
1943	8,399	7,485	10.9	2,336	9,821
1944	6,791	5,985	11.9	2,571	8,556

There was an increase in registration on the basis of credentials in 1944. It is presumed that medical officers returning to civilian practice are making use of this means of obtaining licensure, if they are planning to relocate rather than return to their former practice.

The percentage of failures gradually dropped from 19.3 in 1904, when a great many proprietary medical schools were functioning, to 5.7 in 1930. Improvements in the standards of medical education have resulted in this decrease of failures in licensing examinations. With the migration of physicians to this country beginning in 1936 and the resultant licensure difficulties, the percentage of failures again began to rise, until they reached a peak of 20.7 in 1940. This rise is attributable also to the inability of graduates of unapproved schools to obtain licensure successfully without many failures. In the last two years the number of foreign graduates applying for licensure has considerably decreased. In 1944 also there was a decrease in the number of graduates of unapproved institutions registered.

TABLE 22.—*Graduates of Approved Schools and Others Registered, 1922–1944*

	Graduates of Approved Schools		Others		
	Number	Per Cent of Total	Number	Per Cent of Total	Totals

1944	7,690	89.9	866	10.1	8,556
Total	161,940	88.3	21,516	11.7	183,456

In analyzing this table it should be remembered that the figures represent multiple examinations by individuals in some instances rather than actual additions to the profession.

GRADUATES OF APPROVED SCHOOLS AND OTHERS REGISTERED, 1922-1944

The educational fitness of physicians registered for the practice of medicine is recorded in table 22. In the computation of these figures, schools rated as class A and B by the Council on Medical Education and Hospitals of the American Medical Association since 1907 are classified as approved. In the column "Others" are included individuals who graduated prior to 1907, when the first classification of schools was made, graduates of foreign faculties of medicine, class C graduates, osteopaths given recognition by medical licensing boards and graduates of schools not approved by the Council. In 1928 the classification A, B and C by the Council was discontinued and a list of approved medical schools has since been maintained.

There were 8,556 candidates registered in 1944, of whom 7,690, 89.9 per cent, represented graduates of approved schools and 866, 10.1 per cent, the group designated as others.

In twenty-three years 183,456 were registered, including 161,940 approved graduates (88.3 per cent) and 21,516 others (11.7 per cent). Since 1922 the number of graduates of approved schools has increased

well beyond 4,500, representing more than 80 per cent of those annually registered. Until the influx of foreign graduates in 1936, those in the second group since 1924 have been fewer than 1,000. The number in this group was considerably decreased in 1944 and 323 lower than the figure for 1943.

In computing the figure for 1944 it is revealed that the 8,556 candidates registered represented 7,640 graduates of approved or class A medical schools, 50 were graduates of schools rated in class B at the time of graduation, 350 were graduates of class C or unapproved schools and 516 were foreign graduates and graduates of medical schools before 1907, when the first classification of medical schools was made.

GRADUATES OF UNAPPROVED MEDICAL SCHOOLS REGISTERED, 1939-1944

Graduates of institutions which do not meet the educational standards outlined by the House of Delegates of the American Medical Association and administered

by the Council on Medical Education and Hospitals were registered in nineteen states, Hawaii and Puerto Rico during the last six years. The number so registered will be found in table 23. Figures are given separately for those licensed by written examination and

by endorsement of credentials. In the six years shown 1,087 were registered, 1,027 by examination and 60 by reciprocity or endorsement. In 1944 there were 155 so registered, 153 by examination and 2 without written examination in six states, namely Illinois, Massachusetts, Mississippi, Missouri, Nevada and Virginia.

The large numbers of unapproved graduates licensed in Illinois and Massachusetts result from the nature of the licensing laws in these two states, which accounted for over 90 per cent of these licenses. However, 28 graduates of substandard schools have been licensed in other states in the past four years.

may practice either medicine, surgery or both, as the case may be, if he passes a satisfactory examination before the medical examining board. In Delaware and the District of Columbia osteopaths are granted the right to practice surgery. In Indiana the licenses issued to osteopaths under the 1945 amendment to the medical practice act authorize the holders to practice medicine and surgery. Prior licentiates have been authorized to practice osteopathy, surgery and obstetrics. In Massachusetts the medical practice act, by definition, includes osteopathy in the practice of medicine and does not differentiate the type of license issued to an

* Refer to chart of "Reciprocity and Endorsement Policies" for further data.

1. Certificate of National Board of Medical Examiners and licensure in country in which school of graduation is located.
2. Internship or one year in medical school in United States.
3. Certificate of National Board of Medical Examiners.
4. For graduates of last five years; if more than five years $50.
5. Residence of one year in Delaware.
6. If similar privileges are accorded licentiates of District of Columbia by licensing agency of jurisdiction from which applicant comes.
7. Senior year in class A medical school in United States.
8. Graduates of European medical colleges after July 1, 1936, Switzerland excepted, shall not be eligible for licensure. Graduates prior to this date may be accepted for the regular written and clinical examination after completing rotating internships in approved hospitals in the United States.
9. Enemy aliens not accepted.
10. Application must be filed six months prior to date of examination.
11. Licensed to practice medicine and surgery in country in which school of graduation is located, otherwise required to complete senior year in approved medical school in United States.
12. Diplomates of National Board of Medical Examiners eligible.
13. License to practice medicine and surgery in the country in which the school of graduation is located.
14. Matriculants after Jan. 1, 1940 not accepted.
15. At the discretion of the board.
16. Internship and graduate work.
17. Internship completed in foreign countries after July 1, 1934 not acceptable.
18. Rotating internship in approved hospital in the United States or completion of senior year in class A medical school in the United States.
19. These requirements apply also to graduates of Canadian schools.
20. Graduates from foreign medical colleges accepted if they present also a diploma from an approved medical school in the United States.
21. Provided standard was the same as California on the same date.
22. Degree from an American medical college acceptable to the Medical Council of Delaware required.
23. Diplomates of the National Board of Medical Examiners accepted. Citizenship required.
24. Very limited number contracting to practice in rural districts may be accepted.
25. Effective July 1, 1943.
26. Homeopathic board requires one year internship in homeopathic hospital in the United States.
27. Will consider limited license for applicant with acceptable credits from National Board of Medical Examiners and states maintaining reciprocity.

GRADUATES OF SCHOOLS OF OSTEOPATHY REGISTERED BY MEDICAL EXAMINING BOARDS, 1939-1944

The number of graduates of schools of osteopathy granted the privilege of practicing medicine or surgery or both by the medical examining boards of fourteen states and the District of Columbia for six years (1939-1944) are given in table 24. There have been 856 such individuals registered since 1939, 758 by examination and 98 by endorsement.

In 1944 twelve states registered 165 by examination and 24 by recognition of their credentials, 189 in all. The situation in these fifteen states is as follows:

In Colorado an osteopath receives a license to practice medicine. In Connecticut, any registered osteopath osteopathic applicant. According to a law passed in Nebraska in 1943 "any person now licensed to practice osteopathy may, if application is made prior to July 1, 1948 and upon payment of the prescribed fee, take the first regular examination given after the application is made before the Board of Examiners in Medicine . . . if successful he or she shall receive a license to practice medicine and surgery in the state." In New Hampshire, osteopaths are granted the right to practice medicine and surgery. New Jersey provides that osteopaths licensed prior to Nov. 1, 1941 who furnish proof, prior to that date, of having served for a period of two years as an intern or resident surgeon in an osteopathic or medical hospital approved by the board of medical examiners, of having completed a postgraduate course

of two years in a college of osteopathy or medicine approved by the board, or of having had at least three years of practice in a hospital approved by the board, can be admitted to an examination in pharmacology, therapeutics and surgery and, if successful, can obtain a license to practice medicine and surgery. Since 1941 all osteopathic applicants who have met the requirements of the medical practice act have been licensed to practice medicine and surgery.

A law passed in Ohio in 1943 gives osteopaths who obtain their licenses under that act the right to practice osteopathic medicine and surgery. In Oregon they are granted the right to practice surgery. The medical practice act of Texas provides for the issuing of a license to practice medicine only and osteopaths are issued licenses unrestricted in scope. In Virginia, osteopaths may obtain the right to perform surgery with the use of instruments if they satisfy the board of medical examiners that they have had adequate clinical facilities in their respective college of graduation or by hospital work to enable them to perform such operations. Wisconsin grants osteopaths the privilege to practice surgery and in Wyoming the statutes contain no specific provision for the licensing of osteopaths. The medical practice act of the latter state provides that the certificate issued to all applicants "shall be deemed licenses to practice medicine in all branches in which the applicant has taken examination in the state."

PHYSICIANS EXAMINED ON THE BASIS OF CREDENTIALS OBTAINED IN COUNTRIES OTHER THAN THE UNITED STATES AND CANADA

The Council on Medical Education and Hospitals does not grade or classify medical schools outside the United States and Canada. It does not attempt to evaluate institutions which it is not in a position to visit to determine whether they meet the minimal essentials of an acceptable medical school as outlined by the Council. This was true even before the war.

For a period of twelve years beginning in 1926 the credentials of physicians coming from abroad were verified by the Council through official correspondence with the medical schools directly or through the diplomatic services. Prior to the onset of the war in Europe it was necessary to discontinue this effort, and on the licensing boards rests the responsibility of evaluating the credentials presented by these graduates. In the 1942 edition of the American Medical Directory a symbol in the biographic data of foreign graduates indicates when the information given is the licensing board's record of the credential accepted as meeting the educational qualifications for licensure. The absence of the symbol may be interpreted to indicate that official verification is on file in the office of the Council.

The requirements of candidates for medical licensure in the United States, Alaska, Hawaii and Puerto Rico on the basis of credentials obtained in countries other than the United States and Canada are given in table 25. Eighteen states report that the holders of such credentials are not eligible for licensure. Eighteen states, Alaska, Hawaii and Puerto Rico require full citizenship and ten states naturalization papers as a condition precedent to taking the examination. California, Indiana and the District of Columbia make no reference to citizenship. In some states the recognition or nonrecognition of such individuals is by rule of the board, in others the provision is by statute. Ten states require a certificate from the state board of examiners in the basic sciences. In eighteen states, Alaska, Hawaii and Puerto Rico an internship in a hospital in the United States is a prerequisite. Additional qualifications of individual states are given in footnotes. No state has changed its laws regarding these graduates or relaxed its requirements in recent years.

Table 26 presents figures relating to physicians examined on the basis of credentials obtained in countries other than the United States and Canada by licensing boards in 1944. The figures represent both American and foreign born physicians educated abroad. Ninety-two faculties of medicine and two licensing corporations of nineteen European countries and nine other countries are represented. There were 691 examined by twenty-one states and Puerto Rico, of whom 325 passed and 366, 53.0 per cent, failed. Graduates of the University of Vienna represented the largest group, 135, who were examined in thirteen states, with a failure percentage of 46.7. Five states examined 54 graduates of the University of Berlin, of whom 48.1 per cent failed. More than 35 graduates of the Universities of Paris, Bologna and Lausanne also were examined in the United States last year.

TABLE 27.—*Physicians Examined on the Basis of Credentials Obtained in Countries Other Than the United States and Canada, 1930–1944*

Year	Number Examined	Passed	Percentage Failed
1930	167	92	44.9
1931	158	91	42.4
1932	182	96	47.3
1933	200	129	35.5
1934	285	170	40.2
1935	437	303	30.7
1936	588	382	35.0
1937	920	637	30.8
1938	1,164	716	38.5
1939	1,691	839	50.4
1940	2,088	948	54.7
1941	1,717	698	59.2
1942	1,630	890	45.4
1943	1,031	518	49.8
1944	691	325	53.0
Totals	12,949	6,834	47.2

The greatest number of foreign graduates examined by any one state was 510 in New York, of whom 224 passed and 286 (56.1 per cent) failed. No other state tested more than 37 of these physicians. Fewer than 5 were examined by eleven states. The proportion of failures in seventy-three schools of the total of 94 was 25 per cent or more.

Table 27 records the number of graduates of faculties of medicine abroad examined for medical licensure in the United States in fifteen years, 1930 to 1944 inclusive. In this period 12,949 were examined, of whom 6,834 passed and 47.2 per cent failed. There has been a decrease of 340 in the number examined in 1944 as compared with the previous year. In 1943 there were 599 fewer examined than in the previous year. The percentage of failures however has not changed significantly in recent years. The greatest number of failures occurred in 1941 when 59.2 per cent failed. At no time in this fifteen year period did fewer than 30.7 per cent fail.

From 1936 to 1940 there were large annual increases in foreign graduates examined, so that in 1940 there were over three times as many tested as in 1936. Since 1940 there have been annual decreases. The number last year was 1,397 fewer than that of 1940, but has not yet reached the average number of foreign graduates examined annually prior to 1936 and before the increased migration of foreign physicians to this country from Europe.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Basic science requirements underlying the practice of the healing arts have been established by legislative action in seventeen states and the District of Columbia. A basic science law provides for the establishment of a board of examiners and requires that each person who desires to practice the healing arts appear before that board and demonstrate his knowledge. Such boards are distinct from licensing boards. A certificate of proficiency in the basic sciences does not authorize the possessor to practice the healing art; it enables him only to apply for licensure so to practice.

TABLE 28.—*States Having Basic Science Laws and Year of Enactment*

Arizona	1936	Nebraska	1927
Arkansas	1929	New Mexico	1941
Colorado	1937	Oklahoma	1937

Florida	1939	South Dakota	1939
Iowa	1935	Tennessee	1943
Michigan	1937	Washington	1927
Minnesota	1927	Wisconsin	1925

Connecticut and Wisconsin were the first states to adopt such legislation. Laws were passed in these states in 1925. Other states comprising the group, together with the year of enactment of their basic science law, are recorded in table 28.

The subjects in which examinations are conducted by the respective states and the District of Columbia are shown in table 29. These subjects are specified by statute. The examining boards are not authorized to add any subjects or to refrain from giving an examination in any subject specified by the law. All eighteen boards examine in anatomy, pathology and physiology, sixteen examine in biochemistry, fourteen in bacteriology, eight in hygiene, two in diagnosis and one in public health.

The results of examinations held in these states or the number of certificates issued on the basis of endorsement during the calendar year 1944 are presented in tables 30 and 31. Applying for a basic science certificate, the candidate is not required to mention his school of practice. Official reports which formed the basis for these compilations in some instances included the name of the candidate and but little additional data other than perhaps the name of the high school attended and the present address of the applicant. However, by checking the biographic and medical student records of the American Medical Association and various directories it has been possible to determine the profession of the majority of the candidates. The figures here presented are tabulated in four groups, namely physicians and medical students, osteopaths, chiropractors and unclassified applicants. The latter category includes those for whom it was not possible to determine the profession represented. The unclassified group in Connecticut includes doctors of naturopathy, while in Rhode Island doctors of dentistry represent the unclassified group. The American Medical Association maintains a complete file of physicians and medical students, so that it may be presumed that the unclassified group represents mainly osteopaths and chiropractors which have not been identified by checking the directories and other reference material available.

* Nature of practice undetermined, since names of failures not supplied.

The eighteen basic science boards examined in 1944 a total of 2,763 candidates (table 30). Physicians and medical students represent the greatest number examined. There were 2,284 in this group. There were 122 osteopaths examined, 14 chiropractors, and 329 were placed in the unclassified group. Of all the applicants 22.4 per cent failed. If a candidate failed more than once in a given year he is regarded as a single failure. Of the physicians or medical students

examined, 18.2 per cent failed, osteopaths 51.6 per cent, chiropractors 64.3 per cent and unclassified 35.6 per cent. Among those who were successful there were 1,868 physicians or medical students, 59 osteopaths, 5 chiropractors, and 212 were unclassified. The basic science board of Michigan examined the greatest number of applicants, 443, representing 382 physicians and medical students and 61 others. Of those examined, 30 per cent failed. Iowa, Minnesota and Tennessee respectively examined more than 300 candidates. The percentages of failures in these states were respectively 34.7, 19.8 and 25.8. Four states reported 1 failure each.

Osteopaths were tested in all states except Arizona, Arkansas, Nebraska, Oklahoma, Tennessee and Wisconsin. Chiropractors appeared for examination in four states—Connecticut, Florida, Rhode Island and Washington.

It is the policy of the Arizona Board of Examiners in the Basic Sciences to omit the names of applicants who failed examinations. Failures for this state are recorded only in the total column.

Ten states granted certificates without examination—by reciprocity, endorsement, waiver or exemption. Arkansas, Colorado, Michigan, Minnesota, Nebraska and Oregon waived the written examination for those candidates presenting basic science certificates from other states, while the boards in Iowa, Tennessee and Wisconsin exempted from examination those candidates who had been examined in the basic sciences by professional boards. The District of Columbia certified

without examination diplomates of the National Board of Medical Examiners. Among the states mentioned, the National Board examination was also acceptable to the boards in Arkansas, Colorado, Iowa, Minnesota and Tennessee. These ten states issued 310 certificates without examination, and the boards of all states granted 2,065 certificates after examination.

The figures for Arizona in table 31 do not agree with the previous table discussed, since a number of those examined were issued their certificates in 1945 and will be included in the next annual compilation of basic science tests. Likewise, in Arkansas the majority of those examined were medical students and will receive

their certificates on the completion of their medical training.

The number of successful applicants (2,375) registered by examination, reciprocity, endorsement, waiver or exemption are recorded in table 31. Among the successful candidates were 2,012 physicians, 96 osteopaths, 5 chiropractors and 262 unclassified persons. Wisconsin certified 62 without examination—the greatest number, of whom 33 were physicians, 12 osteopaths and 17 unclassified. No state certified a chiropractor without examination, and five states certified osteopaths without examination.

Altogether, 2,375 candidates received basic science certificates in seventeen states and the District of Columbia in 1944, ranging from 6 in New Mexico to 329 in Michigan.

In table 32 is included the number of candidates examined and certified by basic science boards for each year since and including 1927. In 1928, when five boards were functioning, there were 646 physicians examined, of whom 9.3 per cent failed and 59 other practitioners, of whom 47.5 per cent failed. By comparison, in 1944 the eighteen boards in operation examined 2,284 physicians, of whom 18.2 per cent failed and 465 other practitioners, with 40.6 per cent failures.

In the eighteen year period 19,921 physicians and medical students were examined, of whom 17,403 were successful in these examinations. In the same period 3,137 other practitioners took the test and 1,602 were successful. Of the physicians or medical students examined during these years, 12.6 per cent failed and 48.9 per cent of the other practitioners were unsuccessful. There were in this same period 3,594 physicians and 745 others certified without examination

In eighteen years 23,265 certificates have been granted by basic science boards. These certificates were awarded to 20,919 physicians and medical students and 2,346 other practitioners.

There was created a basic science examining board in Virginia in 1944 to consist of three members appointed by the governor from the faculties of the accredited colleges and universities of the state. None of the members may be a practitioner of any branch of the healing art. The board will cease to function July 1, 1949. It was created solely to examine a group of naturopaths and chiropractors who were practicing in the state without benefit of license during the twelve month period prior to July 1, 1944. Such practitioners must within the five year period either pass an examination given by this board in anatomy, bacteriology, elementary chemistry, pathology and physiology or must pass the examination given by the state board of medical examiners. The basic science board has no function whatever in connection with any other applicant for a license. An examination was scheduled by this board for 1944, but no candidate applied.

The basic science acts in two states were amended in 1945. In Arizona, the act was amended to provide that an applicant who is a citizen of the United States who furnishes proof of a certification, registration, or license issued to him "within any state or territory of the United States in which the requirements for the registration of said applicant at the date of issuance of his license shall be deemed by the board to be equivalent to those of Arizona, shall be eligible for registration by reciprocal endorsement at the discretion of the board." In Tennessee, the amendment in effect imposes a basic science requirement on osteopaths, chiropractors and naturopaths in addition to physicians. Theretofore only the last group named was required to take the examination.

The principle of basic science legislation is to provide a means of insuring that all who seek licensure to care for sick and injured persons shall first possess a reasonable knowledge of the sciences fundamental to the healing art. The enforcement of such laws affects mostly the group classified as "other practitioners." This is particularly significant when one takes into account that the testing of individuals for basic science registration is made by nonmedical examiners. The results demonstrate that, in general, practitioners other than regular physicians are poorly equipped in the fundamentals of medicine and should not be entrusted to care for the health of the people.

Efforts are being made by the American Association of Basic Science Boards to provide information based on experience to states contemplating new basic science board legislation and to develop procedures to facilitate reciprocity arrangements. In some instances basic science certification by reciprocity is unnecessarily difficult because of otherwise unimportant differences in the laws of the various states. The officers of the association are: president, Orin E. Madison, Ph.D., Michigan Board, Detroit; vice president, Charles D. Byrne, Ed.D., Oregon board, Eugene; secretary-treasurer, Ben H. Peterson, Iowa board, Cedar Rapids; executive committee, John S. Latta, Ph.D., Nebraska board, Omaha, and Rev. Nicholas H. Serror, O. P., Rhode Island board, Providence.

NATIONAL BOARD OF MEDICAL EXAMINERS

The certificate of the National Board of Medical Examiners is accepted as an adequate qualification for a medical license by the licensing authorities of forty-four states and the District of Columbia and by the territories and possessions of Alaska, Hawaii, Puerto Rico and the Canal Zone. At present Louisiana exempts diplomates of the National Board from the state examination if they have been licensed in some other state with which Louisiana reciprocates. The provisions of the medical practice laws or state board regulations of a few states are such that diplomates of the National Board are required to take an oral examination in Connecticut, Illinois, Maine, Rhode Island and Wyoming. A brief supplemental examination is required in Michigan. Illinois, Michigan, North Dakota, Pennsylvania and Washington require a rotating internship, while New Jersey recommends this type of service. The National Board certificate is not recognized by the licensing boards of Florida, Montana, Texas and Wisconsin. The states, territories and possessions which will endorse certificates of the National Board of Medical Examiners are recorded in table 33.

TABLE 33.—*States Endorsing Certificates of the National Board of Medical Examiners*

Alabama	Illinois	Nebraska	Puerto Rico

Colorado	Maine	North Carolina	Vermont
Connecticut	Maryland	North Dakota	Virginia
Delaware	Massachusetts	Ohio	Washington
Dist. of Columbia	Michigan	Oklahoma	West Virginia
Georgia	Minnesota	Oregon	Wyoming
Hawaii	Mississippi	Pennsylvania	
Idaho	Missouri		

The examinations of the National Board in the basic sciences are accepted in lieu of the examinations in those subjects given by the basic science boards of Connecticut, Iowa, Minnesota, Nebraska, New Mexico, Tennessee and the District of Columbia.

Diplomates of the National Board are admitted to the final examination of the Examining Board in England, the Triple Qualification Board of Scotland and the Conjoint Board of England. They are also granted recognition by the licensing bodies in Lebanon, South Africa, Spain and Turkey. Diplomates are also admitted without further examination to the Mayo Foundation (Graduate School of the University of Minnesota) and are exempt from some of the qualifications required by the United States Public Health Service.

Requirements for admission to the National Board examinations include a standard four year high school course, two years of acceptable college work including English, physics, chemistry, biology and a foreign language, and a medical education satisfactorily completed in an approved school in this country or Canada. Graduates of the university medical schools of Great Britain and Ireland are admitted to the examination provided these graduates have been licensed to practice in the country in which the school attended is located.

During the last few years there has been an increase in the number of medical schools that are using the

National Board's examinations as part of their own examination and promotion procedure. At some of the schools the students are required to pass part I at the end of the second year and part II at the end of the fourth year. Other schools require that part II be passed at the end of the fourth year. At one school all students are required to pass part I before graduation. Candidates who fail to pass the National Board examinations are given a supplemental examination at most schools. The schools that require practically all of their students to take the National Board's examinations under one plan or another are Albany, Boston, Buffalo, Duke, George Washington, Harvard, Long Island, New York Medical College, Tufts and Yale. In addition to the schools named there are a few others at which those students who voluntarily take and pass the National Board's examinations, either in part I or in part II, are excused from the corresponding final school examinations. This group of schools includes Colorado, Georgetown, Illinois, Loyola, Pennsylvania and Woman's Medical College.

Regarding this plan, the board states that "this practice places additional work and responsibility on the National Board of Medical Examiners. The board believes, however, that such use of its examinations is of definite value to the board because it necessitates that the examination be kept in close step with present medical education in this country. It appreciates the confidence in the fairness and thoroughness of its examinations that is implied by the substitution of the board's examinations for the former college comprehensive examination."

The first examination was given by the National Board in October 1916. From that date and up to and including a test held in June 1921, eleven examinations were held and 268 candidates were certified. The results of each examination during this period are given in table 34. These data, together with subsequent tabulations containing current figures, have been presented annually in THE JOURNAL for twenty-seven consecutive years and are based on official reports received periodically. This information is also included in the biographic file of physicians maintained by the American Medical Association.

Since 1922 the examination of the National Board has been divided into three separate parts which must be taken and completed in the following sequence: part I, consisting of a written examination in the basic sciences; part II, a written examination in five major clinical subjects, and part III, a clinical and practical examination in six major clinical divisions and their component subjects or subdivisions.

The tables that are presented herewith enumerate the results of examinations in parts, I, II and III for each calendar year since 1922, including those who passed and failed examinations and those certified.

During 1944, four examinations were given in parts I and II in various approved medical schools. Examinations in part III are given under the direction of local subsidiary boards at times sufficiently frequent to accommodate all eligible candidates. Such boards have been organized for this purpose in twenty-four centers.

A candidate is eligible for part I who has completed successfully the first two years of the medical course. An incomplete examination is allowed candidates at the end of their second medical year in schools whose third year curriculums include courses in one or two subjects of this part. These subjects may be taken at any examination period after the candidate has completed them in his medical school. They are recorded in these statistics under the heading "Incomplete Examinations."

A candidate is eligible for part II who has completed his four year medical course and has already passed part I.

The figures in tables 35, 36 and 37 cover details of each examination given during 1944 and include some who fail and are reexamined during the same year and those who pass parts I and II in the same year. They represent, therefore, examinations conducted and not individuals examined.

TABLE 37.—*Examinations in Part III, 1922-1944*

1943	1,230	1,213	17	1.4
1944	1,166	1,145	21	1.8
Totals	12,664	12,222	442	3.5

During the year 1944, 4,228 examinations were given in part I; 2,326 were passed and 438, or 10.4 per cent, failed. During 1944 also 1,464 incomplete examinations were given. In part II, 1,404 were given. Fifty-five of this number, 3.9 per cent, were failures. Incomplete examinations are only rarely given in part II. There were none last year.

Since 1922 a total of 31,152 examinations have been given in part I and 16,420 in part II: During this period 19,191 candidates passed part I and 15,233 passed part II. In twenty-three years there have been 3,304 failures in part I, 10.6 per cent, and 1,141 failures in part II, 6.9 per cent. Since the medical schools have been operating on the accelerated plan, candidates taking the examinations of the National Board have greatly increased since 1942. In 1944 the examinations given exceeded the figure for the previous year by 1,572, while in 1943 the number of part II examinations given were in excess of the previous year; those given in 1944 decreased. This variance is again due to the accelerated curriculum.

Part III, the final examination of the National Board, is given when the candidate has received the M.D. degree and has satisfactorily completed an internship in a hospital approved by the Council on Medical Education and Hospitals of the American Medical Association or by the Canadian Medical Association or has served in a laboratory acceptable to the National Board. During the war period candidates may take part III after nine months of internship, but their certificates will be withheld until three additional months have been served as a hospital intern or resident or on active duty in the medical department of the armed forces. In 1944, 1,166 examinations were given, twenty-one of which (1.8 per cent) were unsuccessful tests. Results of examinations in this part during twenty-three years are given in table 37 and indicate that 12,664 were tested, of whom 12,222 were granted certificates. The percentage of

failures in 23 years was 3.5. Since the inception of the National Board in 1916, 12,490 certificates have been awarded.

Physicians who earn the certificate are designated diplomates of the National Board and are privileged to use the designating initials D.N.B.

The figures thus far presented represent examinations given. The number of individuals tested during any one year is recorded for the twenty-three year period in table 38. The classification of "Passed" or "Failed" in cases in which more than one examination has been taken in a given year was based on the results of the last examination during the year in question. For example, if in 1944 a candidate passed part I but later in 1944 failed part II he is computed in the tabulation as having failed. On this basis figures computed indicate that there were 5,363 who took at least one of the tests of the National Board in 1944, as compared with 525 in 1922. The trend has been steadily upward, and last

year the number of candidates was 850 greater than in the previous year. In all, 53,971 individuals were examined in one or more of the annual examinations in the twenty-three years shown, of whom 42,560 passed, 7,275 took incomplete examinations and 4,136, or 7.7 per cent, failed.

The 1,145 physicians certified as diplomates last year represented graduates (table 39) from fifty-two existing and one extinct medical school in the United States, three in Canada and 20 graduates of faculties of medicine abroad. A few of these foreign graduates were diplomates from medical schools in continental Europe who had registered before the National Board discontinued admitting graduates of these schools.

Diplomates licensed to practice medicine on the basis of their credentials increased from 2 in 1917 to 702 in 1944, and 8,925 have been so licensed since the National Board was formed. However, 12,490 have received the certificate of the board. It would appear that 3,565 have not used the credentials as a licensing medium. In 1944 diplomates were granted licenses to practice medicine on the basis of their credentials in thirty-eight states the District of Columbia and Puerto Rico. The number so registered in each state is reported in table 40.

EXAMINING BOARDS IN THE MEDICAL SPECIALTIES

On authorization of the House of Delegates of the American Medical Association, the Council on Medical Education and Hospitals in 1933 formulated minimal standards deemed essential for certification as a specialist. At that time there were five examining boards in the medical specialties functioning: pediatrics, dermatology and syphilology, obstetrics and gynecology, ophthalmology and otolaryngology. Other boards were later organized, and since 1940 fifteen boards have been in operation. These boards are fully approved by the Council.

In addition to regulations relating to the organization and operation of specialty boards, the Council's "Essentials of Approved Examining Boards in Medical Specialties" contains also the minimum qualifications deemed necessary for certification as a specialist. Such qualifications include graduation from an approved medical school, completion of an internship in a hospital approved by the Council, and a period of specialized training in a selected specialty. Each board publishes a booklet containing a brief statement regarding its organization, personnel, purposes and requirements for certification. A statement of these requirements for each board was given in detail in the 1942 Educational Number of THE JOURNAL. Only a few minor changes have been made by some of the boards since these regulations were published in 1942.

The Advisory Board for Medical Specialties was organized in 1933-1934 to coordinate graduate education and certification of medical specialists in the United States and Canada. This board reports directly to its member groups and functions in close collaboration with the Council on Medical Education and Hospitals of the American Medical Association.

The majority of the boards will grant some credit for military service which will compensate in part for the interruption of the graduate training of physicians by military exigencies. The policies adopted by the boards vary. One grants an indefinite amount of credit, to be determined by an evaluation of the experience of individual applicants. Another grants full credit for work done in the surgical division of a regularly constituted Army or Navy hospital. Most boards limit the credit allowed to one year of training and/or one year of experience. The special provisions for military credit made by each board were published in the 1943 Educational Number of THE JOURNAL.

Prospective applicants who are in military services should obtain the booklet entitled "Record of Professional Assignments for Prospective Applicants for Certification by Specialty Boards" from the secretary of the board in the specialty desired. This booklet describes procedures pertaining to military credit and will enable the candidate to keep an accurate account of work done in military service duly certified and will constitute part of the credentials to be submitted on application for certification. One board, the American Board of Internal Medicine, under the direction of Col. William S. Middleton, is conducting special examinations for certification in the European theater of war.

The 9-9-9 program curtails the number of physicians desiring specialty certification. Under this wartime program the various boards will probably allow credit for the actual time spent by the candidate in house officer training in approved hospitals.

Two boards certify candidates in subspecialties. The American Board of Internal Medicine certifies in allergy, cardiovascular disease, gastroenterology and tuberculosis. Similarly the American Board of Surgery certifies specialists in proctology. Regular board certification is a prerequisite for certification in the subspecialty.

A list of the specialty boards and their officers and the number of certificates awarded prior to March 30, 1944 and the number certified until March 1, 1945 respectively appear in table 41. On March 30, 1944 there were 23,444 physicians certified by the fifteen boards and in the following year 1,308 were certified. Up to March 1, 1945 a total of 24,752 certificates had been issued. Included in these figures are 764 who had been certified in the subspecialties mentioned, namely allergy 75, cardiovascular disease 325, gastroenterology 157, proctology 71 and tuberculosis 136.

The greatest number in any one specialty thus far certified were in otolaryngology. In this specialty 3,848 have received the board's certificate since its organization in 1924. The board in ophthalmology, organized in 1917 and the oldest board in existence, has to date certified 2,437 individuals. In the major specialties of general medicine and general surgery, 3,541 and 2,499 respectively have received the certificate of these boards.

A key number has been assigned to each approved board, such as A.B. 1, and the biographic records of physicians published in the American Medical Directory includes by these means reference to those certified by the boards.

The Council on Medical Education and Hospitals works in close collaboration with the various specialty boards in the approval of residencies acceptable for certification. In most instances the Council inspects and evaluates new residencies and approves residency programs jointly with the specialty boards. This program has been established so that approved services may be equally acceptable to the Council and to the respective specialty boards.

There are indications [4] that over 12,000 medical officers will seek specialty certification after the war. The Council, working with specialty boards, hospitals, medical schools and the Committee on Postwar Medical Service, has made notable progress in meeting these educational needs of the future in the advanced training of specialists.

The Council on Medical Education and Hospitals and representatives of the various boards, and the Advisory Board for Medical Specialties, annually hold a joint session for the interchange of ideas and the discussion of problems of mutual interest. These meetings have proved to be worthwhile contributions to the improvement of medical education and medical practice in this country.

TABLE 41.—*Approved Examining Boards in Medical Specialties*

Key No.	Name of Board	Year of Incorporation	Total Certificates Awarded to March 30, 1944	Total Certificates Awarded to March 1, 1945
A.B. 1.	American Board of Pediatrics..... Pres., Edward B. Shaw, 384 Post St., San Francisco Sec., C. A. Aldrich, 115½ First Ave. S. W., Rochester, Minn.	1933	2,220	2,318
A.B. 2.	American Board of Psychiatry and Neurology ..... Pres., Hans A. Reese, Wisconsin Psychiatric Institute, Madison Sec., Walter Freeman, 1028 Connecticut Ave. N. W., Washington, D. C.	1934	1,716	1,899
A.B. 3.	American Board of Orthopaedic Surgery ..... Pres., Frank D. Dickson, 1400 Professional Bldg., Kansas City, Mo. Sec., Guy A. Caldwell, 3503 Prytania St., New Orleans	1934	860	896
A.B. 4.	American Board of Dermatology and Syphilology ..... Pres., Howard Fox, 140 E. 54th St., New York City Sec., George M. Lewis, 66 E. 66th St., New York City	1932	680	710
A.B. 5.	American Board of Radiology..... Pres., John W. Pierson, 1107 St. Paul St., Baltimore Sec., Byrl R. Kirklin, 102-110 Second Ave. S. W., Rochester, Minn.	1934	2,012	2,095
A.B. 6.	American Board of Urology..... Pres., Herman L. Kretschmer, 122 S. Michigan Ave., Chicago Sec., Gilbert J. Thomas, 1409 Willow St., Minneapolis	1935	983	1,018
A.B. 7.	American Board of Obstetrics and Gynecology ..... Pres., W. T. Dannreuther, 580 Park Ave., New York City Sec., Paul Titus, 1015 Highland Bldg., Pittsburgh	1930	1,764	1,871
A.B. 8.	American Board of Internal Medicine ..... Chairman, Reginald Fitz, 319 Longwood Ave., Boston Asst. Sec., W. A. Werrell, 1301 University Ave., Madison, Wis.	1936	3,263	3,541
A.B. 9.	American Board of Pathology..... Pres., Arthur H. Sanford, 102 Second Ave. S. W., Rochester, Minn. Sec., F. W. Hartman, Henry Ford Hospital, Detroit	1936	984	1,047
A.B. 10.	American Board of Ophthalmology Chairman, John Green, 3720 Washington Blvd., St. Louis Sec., S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.	1917	2,336	2,437
A.B. 11.	American Board of Otolaryngology ..... Pres., Harris P. Mosher, 127 Front St., Marblehead Mass. Sec., Dean M. Lierle, University Hospital, Iowa City	1924	3,737	3,848
A.B. 12.	American Board of Surgery..... Chairman, Arthur W. Elting, 119 Washington Ave., Albany, N. Y. Sec., J. S. Rodman, 225 S. 15th St., Philadelphia	1937	2,349	2,499
A.B. 13.	American Board of Anesthesiology Pres., H. Boyd Stewart, 27th Place, Tulsa, Okla. Sec., Paul M. Wood, 745 Fifth Ave., New York City	1938	231	249
A.B. 14.	American Board of Plastic Surgery ..... Chairman, John S. Davis, 135 E. 65th St., Baltimore Sec., James B. Brown, 400 Metropolitan Bldg., St. Louis	1937	160	161
A.B. 15.	American Board of Neurological Surgery Chairm[illegible] 384 P[illegible] Sec., Paul C. Bucy, 912 S. Wood St., Chicago Advisory Board for Medical Specialties Pres., Paul Titus, 1015 Highland Bldg., Pittsburgh Sec., Byrl R. Kirklin, 102-110 Second Ave. S. W., Rochester, Minn.	1940	149	163
	Totals.....		23,444	24,752

Certification in the subspecialties: By the American Board of Internal Medicine: allergy 75, cardiovascular disease 325, gastroenterology 157, tuberculosis 136, total 693. By the American Board of Surgery: proctology 71. Total certified in the subspecialties, 764. These figures are included in the above tabulation.

4. J. A. M. A. **127**: 759-770 (March 31) 1945.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION

535 NORTH DEARBORN STREET - - CHICAGO 10, ILL.

Cable Address - - - - "Medic, Chicago"

Subscription price - - - - - Eight dollars per annum in advance

Please send in promptly notice of change of address, giving both old and new; always state whether the change is temporary or permanent. Such notice should mention all journals received from this office. Important information regarding contributions will be found on second advertising page following reading matter.

SATURDAY, MAY 12, 1945

MEDICAL LICENSURE

In this state board number the Council on Medical Education and Hospitals presents the forty-third annual compilation of data on medical licensure (pp. 101-129). These valuable statistics, covering the calendar year 1944, are widely used by medical schools, licensing and examining bodies, government agencies, medical educators, students and physicians. They were compiled with the generous cooperation of medical and basic science examining boards in the United States, territories and possessions, the National Board of Medical Examiners, the various American boards in the specialties and other agencies. The Council and THE JOURNAL greatly appreciate the cooperation of these agencies in making available this material. Besides publication in THE JOURNAL, a reprint edition is available and given wide circulation. Reprints of certain separate tables are also made and assist the Council in replying to the annual thousands of requests for information on licensure and related subjects.

Primarily as a result of the accelerated program there were 1,211 more licenses issued in 1944 than in the previous year. Of the 9,606 physicians licensed, many previously held licenses elsewhere; 6,933 were licensed for the first time and represent additions to the profession. This is the largest number added to the profession for many years, including the years 1936 to 1941, when large numbers of foreign graduates were licensed and added to the profession in this country. The number of foreign graduates licensed was fewer than at any other time since 1935.

The inadequacy of the educational programs of unapproved schools is clearly reflected in an analysis of failures in licensing examinations. Failures exceeded 45 per cent among the graduates of unapproved medical and osteopathic schools examined by medical examining boards. Approved medical schools had less than 3 per cent failures.

THE NATURE OF ANIMAL VIRUSES

In medical literature the word virus is now used in a special sense to designate certain agents of infectious disease that are not subject to successful study by the usual bacteriologic procedures. The nature and properties of viruses so designated cannot be determined by the morphologic and cultural methods applied with such momentous results to bacteria. Viruses cannot be seen with the light microscope and so far they have not been cultivated outside of living tissue. Scarcely more than a decade ago they were demonstrable only by their power to cause disease. Special and new methods were required to gain some closer insight into their nature and properties. Recent and current results of intensive work with newer methods at Duke University are reviewed by Beard,[1] with special reference to the viruses of vaccinia, equine encephalomyelitis, influenza and rabbit papilloma. By means of air driven, analytical centrifugation of virus infected materials, the viruses just mentioned may be obtained in sufficiently pure forms for study of their chemical and electron micrographic properties. It concerns "complex structures comprised of protein, lipid and nucleic acid." The simplest in composition is the papilloma virus, which appears to be essentially nucleoprotein. There are indications that the vaccinia and influenza viruses are surrounded by semipermeable membranes. The electron microscope is yielding surprising information of the greatest significance with regard to the size, shape and internal structure of the particles of these viruses. Of special interest is the unmistakable differentiation within particles.

These advances in the knowledge of the properties of the animal viruses studied, barely indicated in the foregoing but presented clearly and in detail by Beard, have forced him to abandon his advocacy of the molecular hypothesis of the nature of viruses. The results of the work with the products of the ultracentrifuge do not support the molecular assumption. "The images of the animal virus particles in electron micrographs indicate morphologic characters of the agents obviously similar to those of the relatively highly organized bacteria." But whether viruses are all of the same nature remains to be determined.

Now that purified viruses can be obtained for chemical and physical studies, for biologic experiments and for morphologic examination with the electron microscope, continued work on their nature and on virus diseases, e. g. infantile paralysis, promises results of great significance.

HEARINGS ON THE ELLENDER BILL

The Senate Committee on Military Affairs conducted hearings on the Ellender bill (S. 637) on May 1. This bill (THE JOURNAL, March 10, p. 599) seeks to correct the present policies and regulations, which will either (1) reduce medical school freshmen enrolments materially in 1945 and drastically in 1946 or (2) result in the admission of inferior applicants by some schools. The measure provides for the deferment of qualified premedical students and the assignment of acceptable men in the armed forces to premedical and medical schools. The committee has not yet acted on the bill.

Medical education was represented at the hearings by Dr. Walter Bloedorn of the executive council of the Association of American Medical Colleges and Drs. Harvey Stone and Victor Johnson of the Council on Medical Education and Hospitals of the American Medical Association. There was no representation from the Procurement and Assignment Service, which had previously supported the measure.

A joint statement was made, giving the views of the American Medical Association and the Association of American Medical Colleges. The main outlines of this statement were endorsed by every medical school in the country except Columbia; it demonstrated that utterly inadequate numbers of qualified students will be available for admission to 1946 freshman medical classes. These must come from the following categories: women, men under 18 or physically disqualified and veterans. It will be fortunate if these groups will provide 2,000 qualified students, as compared with the normal admission of about 6,000. For example, a recent survey of eight large universities by Dr. Harold Diehl revealed that only 42 veterans were enrolled there as premedical students who would become available to medical schools before 1947. Of these about 28 were judged to be good material. Normally these eight universities provide 800 to 900 medical school freshmen annually.

The Army, the Navy and the Selective Service System opposed the bill, contending that the deferment of the few thousands involved would seriously hamper the war effort. The measure was also called unnecessary, since it was claimed that adequate numbers would be available without deferments. The opposition, especially General Hershey, repeatedly quoted Dr. Willard Rappleye; they illustrated contentions with Columbia's experiences and prospects as an example. In the critical months to come, the stronger and more favorably situated schools, including Columbia, will suffer least in reduced enrolments. Opposition by this school or its dean to a measure which all other schools believe to be necessary is an unjustifiable performance. Failure of this legislation will make it impossible to maintain enrolments at a level adequate to provide the country with physicians it needs. The action of Dr. Rappleye in lending his aid to the opposition can be characterized as one of reckless irresponsibility.

POLIOMYELITIS IN THIAMINE DEFICIENT MONKEYS

About three years ago it was shown by Foster and her associates [1] of the University of Pennsylvania that the resistance of mice to poliomyelitis virus is increased as a result of thiamine deficiency and that a similar though less pronounced increase in antiviral resistance results from other forms of malnutrition. Similar results were reported by Rasmussen and his associates [2] of the University of Wisconsin. On account of wartime interest in malnutritional immunity, Clark and his associates [3] of the University of Wisconsin have attempted to confirm these seemingly paradoxical results on monkeys.

As a preliminary to the attempted confirmation the Wisconsin biochemist [4] developed a synthetic diet for rhesus monkeys containing optimum amounts of all essential food elements. They found that the signs of mild thiamine deficiency in monkeys are cessation of normal growth, anorexia, apathy and an unkempt appearance. More serious thiamine deficiency is characterized by tremors, ptosis, muscular weakness, cachexia and temporary spastic paralyses. These symptoms are easily alleviated by tube feeding or by the intraperitoneal injection of an adequate amount of thiamine.

To date the immunologic effects of the milder type of thiamine deficiency have been tested on 40 monkeys (four groups of from 4 to 18 each) injected with poliomyelitis virus. Half of the members of each group were maintained on a thiamine deficient diet. Controls were given the optimum synthetic or natural diet. The first series (4 animals) was inoculated intracerebrally with the supernate from a 5 per cent suspension of infected spinal cord. Regardless of diet, all monkeys of this series succumbed to typical poliomyelitis (quadriplegia). There was no essential difference in the incubation period, severity of the symptoms or necropsy findings in the thiamine deficient and adequately fed animals.

In the three remaining groups (7 to 18 monkeys each) inoculation was made by repeated intranasal instillation of 1 cc. of the same supernate. All animals of these three series developed poliomyelitis. The symptoms and necropsy findings in the thiamine deficient monkeys tended to be slightly more severe than in the adequately fed controls. The Wisconsin bacteriologists conclude from these findings that, in contrast to the well confirmed increase in antiviral resistance in thiamine deficient mice, vitamin deficiency does not materially alter poliomyelitis susceptibility in monkeys.

Current Comment

OLEOMARGARINE AND THE COUNCIL ON FOODS AND NUTRITION

Misinterpretation is being placed on the action of the Council on Foods and Nutrition in withdrawing acceptance from individual brands of oleomargarine. Reports published in the periodicals devoted to the interests of the dairy industry and comment stimulated in the public press falsely attribute this action to a lack of confidence in the nutritional value of margarine. Such is not the case. The report of the Council on Foods and Nutrition in THE JOURNAL, Sept. 16, 1944, stated clearly that margarine is considered a general purpose food and therefore outside the Council's scope of acceptance, now limited to "special purpose" foods. For this reason acceptance is no longer granted to margarine. Confidence in the nutritional value of margarine fortified with vitamin A was reaffirmed by the Council at the time acceptance was withdrawn. The attempts of those opposing margarine to cast doubt and suspicion on its food value as a result of the withdrawal of acceptance by the Council are unwarranted and misleading.

HAND BOOKBINDING AS OCCUPATIONAL THERAPY

A recent article on hand bookbinding, by Scheirer,[1] points out the interesting and valuable diversional activity of hand bookbinding in the army convalescent reconditioning program. This particular measure of occupational therapy requires considerable hand skill and facilitates the development of a calm mental atmosphere, which is recognized as having a soothing effect on nervous and irritable persons. The opportunity, the interest and the incentive for hand bookbinding in the occupational therapy program can be provided by instructors and occupational therapists who are willing to prepare food for the mind as well as work for the hands. The tools, materials and technics required are described in Scheirer's contribution.

DETERMINATION OF ALBUMIN AND GLOBULIN IN HUMAN SERUM

One of the limitations in the use of serum albumin and globulin values obtained by salt fractionation is the accuracy of the methods. While the salting out methods give reliable values in normal bloods the errors of the methods are largest in abnormal blood samples, where the clinical need is greatest. Pillemer and Hutchinson[1] recently proposed a method of determining the albumin and globulin content of human serum with the use of methyl alcohol as the reagent. They found that the globulin of human serum can be practically quantitatively precipitated by the addition of methyl alcohol in the cold at a controlled p_H. The albumin remains in solution. In addition they found that the albumin, globulin and the albumin globulin ratios obtained by this method agreed favorably with the values obtained on the same blood by the electrophoretic method. The methyl alcohol method does not require special equipment other than a cold room or an ice box. This accurate procedure is readily carried out and holds considerable promise as a tool in the investigation of blood protein concentration.

AN ADVERTISING BACKFIRE

Seldom have more earnest letters of protest been received in the headquarters office of the American Medical Association than have come in connection with an advertising technic for selling penicillin used during the third week in April by the Cheplin Laboratories, Inc., of Syracuse, N. Y. Apparently telegrams marked "urgent" were sent to the homes of physicians urging them to buy penicillin directly from this company. These telegrams were sent to the homes rather than to the offices of the physicians. In many homes where the telegrams were received sons, daughters and sometimes the father himself were abroad with the armed forces; the telegrams with the heading "urgent" struck consternation. At a time when private messages are so severely restricted, such as congratulations, messages of condolence and those concerning the usual affairs of life, this technic for promoting the sale of a drug would seem to be an infringement of the government's request to aid the war services by diminishing the burden on the telegraph agencies as much as possible. The question of good taste is even more conspicuous.

HYPERSENSITIVITY IN PERIARTERITIS NODOSA AND RHEUMATIC FEVER

In a recent lecture before the Institute of Medicine of Chicago, Rich[1] discussed the role of hypersensitivity in disease, particularly in periarteritis nodosa and rheumatic fever. Widespread periarteritis nodosa was found by him in patients with pneumonia who died after treatment with antipneumococcus serum and a sulfonamide drug, singly or combined. The evidence pointed to the production of periarteritis nodosa by hypersensitive reactions of the serum sickness type induced by the foreign serum or by sulfonamides. Rich has shown that typical periarteritis nodosa may develop in experimental serum disease of rabbits following the injections of large amounts of foreign serum, but the animal has not been rendered hypersensitive to sulfonamides, possibly because the drug does not unite with rabbit plasma protein to form an abnormal antigenic molecule. From clinical observations we have learned that in human beings sulfonamides may act as powerful sensitizers. Rich states that since the introduction of sulfonamides in 1936 there has been an increase in the number

1. Rich, A. R.: The Role of Hypersensitivity in the Pathogenesis of Rheumatic Fever and Periarteritis Nodosa, Proc. Inst. Med. Chicago **15**: 270 (March) 1945.

of cases of periarteritis nodosa coming to necropsy in the Johns Hopkins Hospital. He cautions against the ungoverned use of sulfonamides for minor ailments and urges that patients under sulfonamide treatment be watched carefully so that the drug may be discontinued immediately on the first appearance of symptoms of hypersensitiveness. Undoubtedly other forms of sensitization than by foreign serum and sulfonamides may result in periarteritis nodosa. Rich refers to the relationship that has been observed between this vascular disease and asthma. In every case of periarteritis earnest effort should be made "to determine the inciting antigen." In the course of his experiments on sensitized rabbits Rich found cardiac lesions which closely resembled those of rheumatic fever. The focal changes in the collagen of the connective tissue, the Aschoff body, the inflammatory lesions, the small foci of necrosis in the cardiac muscle, characteristic of rheumatic fever, were all found in rabbits subjected to reactions of the serum disease type. These facts support the view that the lesions of rheumatic fever result from reactions to antigen to which the body is sensitized. While the hemolytic streptococcus may be the most common source of the antigen, the possibility that other antigens may be concerned in some of the cases cannot now be excluded. It appears then that in periarteritis nodosa hypersensitivity plays a causative role, and there is good evidence that this is the case also with respect to lesions in rheumatic fever. There are indications, according to Rich, that hypersensitivity may be a factor in the genesis of rheumatoid arthritis, lupus erythematosus, certain forms of purpura and glomerulonephritis in some cases.

SIR THOMAS LEWIS

The death of Sir Thomas Lewis on March 17 ended a distinguished career highlighted by pioneer accomplishments in the application of scientific standards and methods to clinical practice. A mere recital of Lewis's achievements is impressive; his influence, however, rested largely on his use of the experimental method to analyze problems of the patient. Early interest and training in physiology and close friendship and association with James Mackenzie no doubt led Sir Thomas to the new science of electrocardiography. In vascular physiology Lewis and his colleagues elucidated the mechanism of Raynaud's disease, acrocyanosis, intermittent claudication and angina pectoris. Later he became interested in the mechanism of pain. Lewis, his colleagues and his students have contributed to the fundamental knowledge of physiology on which rational therapeutics is based. Throughout his life of active research Sir Thomas recognized the needs of the student and practitioner by contributing a number of exceptional books, most of them widely known in this country, including "Clinical Disorders of the Heart Beat," "Clinical Electrocardiography" and "Diseases of the Heart." He was editor of the medical periodical *Heart* from its founding in 1908 and of this journal's successor, *Clinical Science,* which in the change of names reflects Lewis's broad interests and physiologic approach to medical problems. The death of Sir Thomas Lewis is a loss to the medical world. His influence on methods of clinical research perhaps even more than his own accomplishments has made an indelible impression on medical science which will persist for decades.

INTRAVENOUS ALCOHOL ANESTHESIA AS USED IN RUSSIA

Verkhovskaya,[1] pointing out that alcohol, like chloroform and ether, belongs to those poisons which act by paralysis of the central nervous system, emphasizes that alcohol has the advantage over chloroform and ether that it is almost completely metabolized to carbon dioxide and water. In narcosis produced by administration of alcohol, sleep begins quickly and analgesia soon follows. The toxic dose of alcohol is 7.7 cc. per kilogram of body weight. The dose producing analgesia and sleep varies from 1.5 to 3.0 cc. Thus the difference between the toxic and the therapeutic dose is 4.7 to 5.2 cc. The margin of safety is considerably less for ether and chloroform. The difference between the toxic and therapeutic blood concentrations is 1.5 mg. for chloroform and 4 mg. for ether per hundred cubic centimeters. Two cc. of a 1 per cent solution of morphine is given to the fasting patient half an hour before the operation. Intravenous administration of 1 part of 95 per cent alcohol with 2 parts of 5 per cent glucose solution is started on the operating table. The average dose for complete narcosis is 2 to 2.5 cc. per kilogram of body weight. Thus a person weighing 60 Kg. requires 120 cc. of alcohol and 240 cc. of 5 per cent glucose solution. The mixture is prepared on the day of operation. The glucose solution is sterilized and the required amount of alcohol is added just before use. The standard apparatus for blood transfusion is utilized for the infusion, which is given slowly for fifteen to twenty minutes. When sleep sets in, the rubber tube is clamped to stop the infusion. The clamp is released if signs of awakening appear before the operation is finished, and the drip is resumed. When deep anesthesia has set in, the vein is flushed with 30 to 40 cc. of isotonic solution of sodium chloride to prevent possible thrombophlebitis. Sleep begins following the introduction of 40 to 60 cc. of alcohol. The stage of excitement is passed without difficulty and sleep sets in quickly. The conjunctivas, face and neck become red; the pupils contract and stop reacting to light. Respirations become even and steady and the pulse is of good volume. Sleep lasts from two to five hours. On awakening the patient is irrational and requires special observation. Thirty operations have been performed at an evacuation hospital under intravenous alcohol anesthesia. Complications noted were vomiting in 6 per cent of the cases, temporary retention of urine, transitory headache and the occasional appearance of albumin and flat epithelial cells in the urine, which disappeared in a few days; 20 to 30 red blood cells per high power field also were found. Verkhovskaya concludes that alcohol narcosis is an inexpensive method, devoid of the defects of some other methods of anesthesia.

MEDICINE AND THE WAR

ARMY

HARMON GENERAL HOSPITAL IS TROPICAL DISEASE CENTER

Harmon General Hospital, Longview, Texas, was recently designated for the treatment of tropical diseases. The only other army tropical disease center is Moore General Hospital, Swannanoa, N. C. Lieut. Col. Francis R. Dieuaide, chief of the Tropical Disease Branch, Medical Consultants Division, Office of the Surgeon General, stated that the medical staff of Harmon General Hospital has for some time been engaged in a study of relapsing malaria which has resulted in a permanent contribution to the knowledge of the disease. This study is now being extended to other tropical diseases which are rare in this country, such as filariasis, schistosomiasis and dysentery. Col. Gouveneur V. Emerson is commanding officer of Harmon General Hospital, Lieut. Col. Worth B. Daniels is chief of the medical service and Lieut. Col. Stuart W. Lippincott is chief of the laboratory division.

HEADS NEW DEPARTMENT AT SCHOOL OF AVIATION MEDICINE

Major R. Lee Clark, former fellow in surgery of the Mayo Foundation, was recently appointed director of the newly formulated Department of Surgery of the School of Aviation Medicine, Randolph Field, Texas. Major Clark, who was transferred to Randolph Field from Wright Field at Dayton, Ohio, was also appointed director of surgical research for the Army Air Forces. In addition to his new posts he will continue as the surgical consultant of the Army Air Forces for the Central District of the United States, which area includes Texas, Louisiana, Arkansas, Oklahoma, Colorado, Missouri, New Mexico, Iowa, Minnesota, North Dakota, South Dakota and Nebraska.

HOSPITAL SHIP NAMED FOR FRANCES Y. SLANGER

The U. S. A. H. S. *Frances Y. Slanger* will enter active service under the operation of the Transportation Corps in a short time and will be the largest and fastest American hospital ship afloat. It was formerly the Italian luxury liner *Saturnia*. Second Lieutenant Slanger, army nurse for whom the ship is named, was the seventh nurse to lose her life in this war and was the first American nurse to be killed in the European theater of operations.

TWINS IN THE ARMY MEDICAL CORPS

The military careers of Col. Ziba L. Henry and Lieut. Col. William H. Henry, twins in the Army Medical Corps, both of whom graduated from the Starling Medical College, Columbus, in 1903, illustrate the extent to which identical twins resemble each other.

Col. Ziba L. Henry was ordered to active duty in the Medical Reserve Corps in 1908 and continued on active duty until World War I started, when he was rapidly promoted to captain, major and lieutenant colonel. He was retired for age in 1936 as a lieutenant colonel but again assigned to active duty in 1941 and later promoted to colonel and was retired because of disability in 1943.

Lieut. Col. William H. Henry entered the Medical Corps as a first lieutenant early in 1917 just after the declaration of war. He was promoted to captain and major and served for four years as a major, with one year's service in England, France and Russia. He was discharged in December 1922 and appointed as major in the Reserve Corps and still later to lieutenant colonel, which rank he still holds.

Both were commissioned as majors in the Medical Corps of the Regular Army in 1920. Both served tours of duty in the Philippines. They graduated from literary and medical school at the same time and both did general practice for a number of years. They are identical twins and few except their intimate friends can tell them apart.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel Richard L. Meiling

Lieut. Col. Richard L. Meiling, formerly of Columbus, Ohio, was recently awarded the Legion of Merit "for services as air evacuation officer and executive officer, operations division, Office of the Air Surgeon, from Sept. 22, 1942 to July 11, 1944. Because of his thorough medical professional knowledge as well as his knowledge of air forces operations and organization, he was given the difficult and responsible assignment of preparing studies and plans for the organization of the first organized Air Evacuation Service. His enthusiasm, diplomacy and complete knowledge of his task enabled him to 'sell' this program to War Department chiefs of staff, theater commanders and our Allies. An ardent advocate of air evacuation, he has been ever active in the development of medical equipment peculiar to air evacuation. Today air evacuation squadrons are performing these duties in each theater of war. They have evacuated wounded from the South Pacific, Africa, Sicily, Italy and Normandy and in the Continental United States. Their contribution to the improvement of the morale of all personnel, as well as an aid to the tactical commander in the rapid evacuation of noneffectives, has proved to be of inestimable value in the prosecution of the war. His superior organizational ability and efficiency in the development of air evacuation of the Army Air Forces reflect the highest credit on himself and the armed forces of the United States." Dr. Meiling graduated from the Ludwig-Maximilians University Medical Faculty in 1937 and entered the service Oct. 7, 1940.

Lieutenant Colonel John D. Handley

The Bronze Star was recently awarded to Lieut. Col. John D. Handley, formerly of Hodgenville, Ky. The citation accompanying the award read "for meritorious service in connection with military operations against an enemy of the United States from July 20, 1944 to Dec. 20, 1944. Colonel Handley, serving as chief of medical service, 101st Evacuation Hospital, worked untiringly with approximately 12,000 patients passing through the hospital during the period named. His assignment of officers and men of his section resulted in most effective and frictionless institutional operation. Knowledge of latest standards of diagnosis and treatment left few instances requiring assistance from outside sources. Good humor and rare tact kept morale at high pitch in spite of fatigue and nervous tension due to long continued activity. Colonel Handley has displayed and exemplified the highest traditions of the Medical Department of the United States Army." Dr. Handley graduated from the University of Louisville School of Medicine in 1928 and entered the service June 12, 1942.

Colonel Ira V. Hiscock

Col. Ira V. Hiscock, officer in charge of the Public Health Section, Economics and Relief Branch of the Civil Affairs Division, was recently presented the Legion of Merit for his work in typhus control in liberated countries, particularly in Italy, from April 1943 to February 1945.

Colonel Hiscock was placed on inactive duty April 12 to become chairman of the Department of Public Health at Yale

University. He was professor of public health in the School of Medicine at Yale prior to entering the service.

The citation accompanying his award read:

"For exceptionally meritorious conduct in the performance of outstanding services from April 1943 to February 1945. As officer in charge of the Public Health Section, Economics and Relief Branch of the Civil Affairs Division, Colonel Hiscock with rare foresight and ability supervised all matters relating to health services, hospitals, medical services and sanitation pertaining to the civilian populations in liberated or occupied countries and acted as liaison between the Office of the Surgeon General and Civil Affairs Schools and the School of Military Government at Charlottesville, Va.

"His advice to the Civil Affairs Division on all medical matters within its jurisdiction and to the G-5 Division of the theaters of operation and tactical command headquarters, together with the prompt action taken by him, prevented the serious consequences which might have resulted from the dangers of disease to which our troops were exposed.

"The effectiveness and adequacy of the plans made and executed under Colonel Hiscock's supervision were demonstrated in the typhus outbreak that occurred in Naples. This community had been devastated by the enemy; the populace was suffering from malnutrition and was living in unspeakable filth without water and sewerage facilities and lacking elementary sanitary means of modern civilization; it was a potential breeding place for disease. Colonel Hiscock's plans to meet just such a contingency prevented what might have been a catastrophe. As an indelible tribute to his genius the records show that, of the thousands of troops stationed in and passing through the Naples area, not a single American soldier died of typhus."

Major Ralph H. Riegelman

The Bronze Star was recently awarded to Major Ralph H. Riegelman, formerly of Milwaukee, Wis., "for meritorious achievement as a group surgeon of a heavy bomb group and station surgeon of a station hospital in the North African and European theaters of operation from September 1942 to the present day. With no precedent to guide him and only limited personnel to work with, Major Riegelman established a most efficient station hospital to satisfy the many needs of an extensive combat operations program. By his diligence and devotion to duty he has successfully cared for the health of the group while operating from North Africa under adverse conditions. His skill, judgment, initiative, foresight and devotion to duty are most praiseworthy and reflect great credit on himself and the armed forces of the United States." Dr. Riegelman graduated from Marquette University School of Medicine, Milwaukee, in 1941 and entered the service in December 1940.

Captain Leo Lefkowitz

The Bronze Star was recently awarded to Capt. Leo Lefkowitz, formerly of Woodside, N. Y. The citation accompanying the award read "for meritorious service in connection with military operations against the enemy as orthopedic surgeon, 44th Evacuation Hospital, Semimobile, from June 19, 1944 to Dec. 4, 1944 in France and Belgium. Captain Lefkowitz performed numerous operations on all types of battle casualties with superior surgical skill and versatility. In many instances, after laboring for long periods of time in surgery, he voluntarily remained on duty to give expert postoperative care to his patients. By his untiring efforts and professional ability Captain Lefkowitz contributed materially to the success of his hospital, thus reflecting credit on himself and the military service." Dr. Lefkowitz graduated from Columbia University College of Physicians and Surgeons, New York, in 1924 and entered the service April 1, 1943.

Major Jay E. Tremaine

Posthumous award of the Bronze Star was recently made to Major Jay E. Tremaine, formerly of Ajo, Ariz., for "service from March 2 to Sept. 7, 1944. While at Lasang, Davao, Philippine Islands, he patiently and untiringly served American prisoners of war who were constantly in need of medical assistance. On board a prison ship, the men were crowded, starved and overheated, but his cheerful attitude and optimism encouraged them and inspired them with the will to survive. When the ship was torpedoed he lost his life. His courageous services in the face of almost unbearable conditions were an invaluable contribution to the welfare of his comrades." Dr. Tremaine graduated from Rush Medical College, Chicago, in 1930 and entered the service April 2, 1941. He was killed in action when the ship was sunk Sept. 7, 1944 off the Philippine Islands.

Colonel Lyle S. Powell

Col. Lyle S. Powell, formerly of Lawrence, Kan., and at present medical officer for a field headquarters of the Chinese Combat Command in south central China, was recently awarded the Bronze Star "for meritorious service." Dr. Powell also served overseas for two years in the first world war, serving first as commanding officer of the 99th Aero Squadron and later as group commander of the 99th and 104th squadrons. He was awarded the Legion of Honor with two stars. Dr. Powell graduated from the University of Nebraska College of Medicine, Omaha, in 1925 and entered the service Sept. 22, 1942.

Lieutenant Colonel Melvin F. Huth

A citation for the "efficient, rapid and uninterrupted support the medical battalion rendered the division during its rapid attack through the Vosges Mountains and its subsequent attack north across the German border" was recently awarded to Lieut. Col. Melvin F. Huth, formerly of Baraboo, Wis. Colonel Huth is commanding officer of the medical battalion which received the commendation for its ceaseless devotion to duty and care of the wounded. He graduated from the University of Wisconsin Medical School, Madison, in 1933 and entered the service in January 1941.

Major Howard A. Lowy

Major Howard A. Lowy, formerly of Creve Coeur, Ill., and now serving as assistant to the surgeon at the headquarters of the Chinese combat command near Kunming, was recently awarded the Presidential Unit Citation for his service with the India-China Wing of the Army Transport Corps and is also entitled to wear two bronze stars on his Asiatic-Pacific Campaign Ribbon, one for service in India and the other for service in China. Dr. Lowy graduated from the University of Illinois College of Medicine, Chicago, in 1940 and entered the service in October 1942.

Captain William H. Reiff

Capt. William H. Reiff, formerly of Oklahoma City, was recently awarded the Bronze Star "for meritorious service in connection with military operations against the enemy in France, Luxembourg, Belgium and Germany during the period July 3, 1944 to March 10, 1945." Dr. Reiff graduated from the University of Oklahoma School of Medicine, Oklahoma City, in 1941 and entered the service July 1, 1942.

Captain Fred J. Ansfield

Capt. Fred J. Ansfield, formerly of Glidden, Wis., was recently awarded the Silver Star and the Bronze Star. His division was awarded the Presidential Citation for superb fighting. Dr. Ansfield graduated from the University of Wisconsin Medical School, Madison, in 1933 and entered the service Oct. 29, 1942.

Major Edouard E. Lyon

The Soldier's Medal was recently awarded to Major Edouard E. Lyon, formerly of Toledo, for heroism. He rescued two soldiers from drowning when a landing craft overturned during a landing operation in the Southwest Pacific. Dr. Lyon graduated from Northwestern University Medical School, Chicago, in 1929 and entered the service Aug. 31, 1942.

Captain William W. Schildecker

Capt. William W. Schildecker, formerly of Pittsburgh and now with the 5th Army Ski Troops in the mountains of northern Italy, was recently awarded the Bronze Star and the Purple Heart. Dr. Schildecker graduated from the University of Pittsburgh School of Medicine, in 1943 and entered the service Jan. 1, 1944.

NAVY

SIX HOSPITAL SHIPS TO JOIN NAVY

The U. S. S. *Tranquility*, first of a new class of navy hospital ships being converted from Maritime Commission C-4 hulls, was recently inspected at the Atlantic Basin Iron Works in Brooklyn. The Navy is acquiring six of the 15,000 ton air conditioned ships with a speed of 17½ knots. The vessels will have hospital beds for 802 patients, including 742 enlisted men and 60 officers. Under emergency conditions, however, the craft may carry several hundred more cases. A ship's company will consist of 58 officers, 30 nurses, 2 women Red Cross workers, 24 petty officers, 230 crew members and 238 hospital ratings. The *Tranquility*, which will be commissioned soon, will be commanded by Capt. Merritt D. Mullen, U.S.N.R. The senior medical officer will be Capt. B. W. Hogan, U.S.N., with Lieut. Sylvia Koller, U.S.N., as chief nurse.

PLAQUE IN MEMORY OF LIEUTENANT F. B. BEGOR

McGill University has prepared a plaque in memory of the late Lieut. F. B. Begor U.S.N.R. Medical Corps, which is to be placed in the ward room of the U. S. destroyer bearing Dr. Begor's name. The plaque reads "In proud memory of Fay Broughton Begor, M.D., C.M., (McGill) Lieutenant (jg), Medical Corps, U.S.N.R., who was posthumously awarded the Navy Cross for his gallantry under fire on the beaches of Lae, New Guinea, in September 1943, and in tribute to the four hundred graduates of McGill University who are serving with the armed forces of the United States of America."

NAVY AWARDS AND COMMENDATIONS

Lieutenant (jg) Edgar M. Rector

The Silver Star Medal was recently awarded to Lieut. (jg) Edgar M. Rector, formerly of Ann Arbor, Mich., "for conspicuous gallantry and intrepidity in action against the enemy on the islands of Saipan and Tinian, Marianas group, while serving as a medical officer with an infantry battalion. On July 3, 1944, when the entire front line was forced to withdraw because of heavy enemy fire, Lieutenant (junior grade) Rector remained forward of our lines until late at night, administering first aid and plasma to the wounded until they could be evacuated. Later on Tinian, despite a painful wound in his hand, he moved forward under fire to aid a wounded Marine who could not be evacuated. Lieutenant (junior grade) Rector received a serious chest wound at this time. His outstanding courage and disregard for his own safety were in keeping with the highest traditions of the United States Naval Reserve." Dr. Rector has also been the recipient of the Silver Star, the Purple Heart and a Presidential Unit citation. He graduated from Harvard Medical School, Boston, in 1941 and entered the service Nov. 1, 1943.

Lieutenant Michael J. O'Grady

Lieut. Michael J. O'Grady, formerly of Nutley, N. J., was recently awarded the Bronze Star for bravery in the Southwest Pacific. The citation read, in part, "After receiving an emergency call from a patrol craft he entered a small open boat and with disregard for his own safety made his way to stricken craft through intense crossfire, rendering medical aid and saving many lives." Dr. O'Grady graduated from Georgetown University School of Medicine, Washington, in 1933 and entered the service in November 1942.

Lieutenant Jesse John Wimp

The Bronze Star was recently awarded to Lieut. Jesse John Wimp, formerly of Kirksville, Mo. The citation accompanying the award read "for meritorious service as medical officer attached to a Marine Battalion in the Empress Augusta Bay Area, Bougainville, Solomon Islands, from Nov. 7, 1943 to Jan. 20, 1944. With the assistance of one junior officer and a small enlisted staff, Lieutenant Wimp established four organizational sick bays and rendered medical assistance not only to his own battalion but to all other troops in the area. Although suffering from a painful illness during the entire period, he worked tirelessly, treating or supervising the treatment of more than 300 sick and wounded a day despite the ever present danger from constant attacks by enemy bombers and artillery. His courageous devotion to duty and inspiring leadership were in keeping with the highest traditions of the United States Naval Service." Dr. Wimp graduated from Washington University School of Medicine, St. Louis, in 1933 and entered the service Sept. 7, 1942.

Lieutenant Paul Ashley

Lieut. Paul Ashley, formerly of Chicago Heights, Ill., was recently awarded the Bronze Star "for distinguishing himself by heroic and meritorious achievement in connection with operations against the enemy as division medical officer aboard an aircraft carrier on Nov. 25, 1944 off the coast of the Philippines while this vessel was under attack by Japanese aircraft. During and after a heavy aerial assault by Japanese aircraft he displayed exceptional ability and untiring devotion to duty which contributed greatly to the recovery of many wounded. His relentless zeal in the execution of his duties was exemplary and at all times in keeping with the highest traditions of the United States Naval Service." Dr. Ashley graduated from Rush Medical College, Chicago, in 1937 and entered the service Nov. 30, 1942.

Lieutenant (jg) Francis Ambrose Lagorio Jr.

Lieut. (jg) Francis Ambrose Lagorio Jr., formerly of Chicago and now battalion surgeon of the 7th Marines, 1st Division, has been commended for heroism in the bitter fighting on Peleliu Island last September and October by the Marines' commanding officer, Lieut. Gen. H. M. Smith. The citation states that "Lieutenant Lagorio organized and directed stretcher bearers to the front and to the rear. . . . He . . . contributed greatly to the ultimate combat efficiency of the battalion." Dr. Lagorio graduated from Loyola University School of Medicine, Chicago, in 1943 and entered the service early in 1944.

Dr. Paul E. Walker

Dr. Paul E. Walker, formerly of Louisville, Ky., was recently awarded the Legion of Merit for "exceptionally meritorious conduct" as medical officer on the assault transport *Cavalier* in the Pacific. Dr. Walker graduated from the University of Tennessee College of Memphis in 1931 and joined the Public Health Service in 1934. He was stationed at the Marine Hospital in Louisville, Ky., prior to his overseas assignment. The citation stated in part that Dr. Walker "displayed exceptional ability in organizing and training the medical department of the assault transport during operations at Saipan and Tinian Islands and at Leyte."

Captain Charles P. Archambeault

The Bronze Star was awarded to Capt. Charles P. Archambeault, formerly of Washington, D. C., and now with the 3d Marine Division somewhere in the Pacific. He was cited for sending troops into battle in good physical condition and training medical personnel who held losses from sickness and wounds down to a minimum during the Guam campaign. Dr. Archambeault graduated from Albany (N. Y.) Medical College in 1918 and entered the service Nov. 12, 1920.

Commander Alpha Rees Klopfenstein

Comdr. A. Rees Klopfenstein, formerly of Toledo and now commanding officer of a Navy hospital which was in operation on Saipan two days after the initial landings, according to an overseas dispatch from the U. S. Marine Corps, was awarded the Bronze Star for his share in this achievement. Dr. Klopfenstein graduated from the University of Michigan Medical School, Ann Arbor, in 1925 and entered the service Jan. 2, 1942.

Commander Fred Shapiro

Comdr. Fred Shapiro, formerly of Chicago, was recently awarded the Legion of Merit at the U. S. Naval Hospital in Seattle, where he is now staff surgeon, for serving as marine regimental surgeon during the Tarawa, Gilbert Islands, Saipan and Tinian operations. The citation read, in part, "his skill as a surgeon contributed greatly to the saving of many lives.

During this period he personally took care of 262 compound fractures, displaying outstanding skill and untiring effort in the care of the wounded." Dr. Shapiro graduated from the University of Illinois College of Medicine, Chicago, in 1931 and entered the service March 30, 1942

Commander Carnes Weeks

The Navy's Commendation Ribbon was recently presented to Comdr. Carnes Weeks, formerly of New York. The citation accompanying the ribbon read "For outstanding service in the line of his profession while serving as fleet and staff surgeon on the staff of commander Third Fleet during a series of highly successful offensive attacks on the western Carolines, the Bonins, Nansei Shoto Islands, Formosa, Luzon-Visayas-Mindanao areas in the Philippine Islands, French Indo-China bases and Hong Kong-Canton-Hainan areas in support of Central and Southwest Pacific Amphibious operations covering the period of Aug. 24, 1944 to Jan. 26, 1945. Commander Weeks assisted materially in planning for the evacuation of the wounded in connection with the amphibious operations conducted by the Western Pacific Task Forces (Third Fleet) against the Palaus and Ulithi Atoll. In addition thereto this officer, throughout the period of operations, was instrumental in the maintenance of the morale and well-being of the commander, members of his staff and the Flag complement during a most difficult and arduous cruise. His conduct throughout was in keeping with the highest traditions of the United States Naval Service." Dr. Weeks graduated from Columbia University College of Physicians and Surgeons, New York, in 1923 and entered the service Feb 28, 1942.

MISCELLANEOUS

SURPLUS MEDICAL AND SURGICAL EQUIPMENT FOR CIVILIAN USE

Announcement was made through the April 28 issue of the *Surplus Reporter*, published monthly by the Department of Commerce, Office of Surplus Property, formerly Treasury-Procurement, of a large variety of surplus surgical equipment and supplies now available to tax supported institutions and established firms selling to the profession Included in the list of items offered are 15 Graefe's largest size Strabismus hooks, 163 Tyrroll iris hooks, an assortment of nasal, ear, sphenoid, tonsil and other knives, and several lots of minor operating scalpels, some with two handles and twelve blades in a canvas case, some with 1 inch, 1½ or 2 inch sharp point blades. Also included are nasal, bandage, dissecting, surgical, ganglion and operating scissors, 22 intestinal clamps, 176 hemostatic and 11 tenaculum forceps and 19 used tonsil hemostats of the clamp type. The catalogue also lists 35 galvanized iron food trucks equipped with 20 cold trays and 110 alternating current three phase heater and compact server, suitable for use in institutions or hospitals. A list of the regional offices of surplus property was published in the March 17 issue of THE JOURNAL. At that time the program was under the Treasury Department. It has since been transferred to the Department of Commerce, Office of Surplus Property, the offices remaining the same.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

(Continuation of list in THE JOURNAL, May 5, page 37)

CALIFORNIA

Hospital of the Good Samaritan, Los Angeles Capacity, 455; admissions, 10,695. Miss Margaret J. Wherry, R N, Superintendent (Resident—pathology, July 1, disqualified for military service).

ILLINOIS

Norwegian American Hospital, Chicago Capacity, 232, admissions, 6,151. Mr. James E. Moore, Superintendent (intern, July 1).

LOUISIANA

Shreveport Charity Hospital, Shreveport Capacity, 790; admissions, 12,172. Dr. Edgar Galloway, Superintendent (2 interns, July 1).

NEW JERSEY

Mercer Hospital, Trenton. Capacity, 274, admissions, 6,115. Mr. George H. Buck, Superintendent (interns)

NEW YORK

Coney Island Hospital, Brooklyn Capacity, 300, admissions, 5,519. Dr. Saul M. Penner, Medical Superintendent (5 interns, July 1 and August 1).

NORTH CAROLINA

Watts Hospital, Durham Capacity, 225, admissions, 7,527. Mr. Samuel B. Forbus, Superintendent (assistant resident—surgery, disqualified for military service).

PENNSYLVANIA

Women's Homeopathic Hospital, Philadelphia Capacity, 400, admissions, 3,197. Miss Mary A Smith, Administrator (intern, disqualified for military service).

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Station Hospital, Fort Ord: Experiences with Infectious Diseases in Army Camps in England, Dr. Gordon E. Hein, May 19; Suppuration of the Chest, Dr. Clayton G. Lyon, May 19.

U. S. Naval Hospital, Mare Island: Abdominal Surgery, Dr. Thomas F. Mullen, May 18; Surgery of the Gallbladder, Dr. H. Glenn Bell, May 25.

Illinois

A. A. F. Regional Hospital, Scott Field: Psychosomatic Medicine, Dr. Robert E. Britt, May 17; X-Ray Findings in Chest Injuries, May 31.

Nebraska

Station Hospital, Army Air Base, Kearney: Hematuria, Dr. W. Joseph McMartin, May 21; Management of Common Anorectal Conditions, Dr. Louis E. Moon, May 21; Recent Advances in Diabetes Mellitus, Dr. John R. Kleyla, May 21.

South Dakota

Station Hospital, Army Air Base, Rapid City: Common Lesions of the Fundus Oculi, Dr. Charles M. Swab, May 17; Psychoneuroses and Psychosomatic Disorders, Dr. A. E. Bennett, May 17; Surgical Management of Carcinoma and Ulcer of the Stomach, Dr. J. Dewey Bisgard, May 17.

Station Hospital, Army Air Base, Sioux Falls: Thrombocytopenic Purpura, Dr. Joseph D. McCarthy, May 29; Radiation Treatment of Benign and Inflammatory Conditions, Dr. Roy W. Fouts, May 29; Granulopenia, Dr. Warren Thompson, May 29.

MEDICAL AND SURGICAL RELIEF COMMITTEE OF AMERICA

The Medical and Surgical Relief Committee of America, Inc., 420 Lexington Avenue, New York 17, recently donated 12 million units of penicillin to the French Hospital of Ste. Anne in Toulon, France, in answer to an appeal received from Vice Admiral Raymond Fenard, chief of the French Naval Mission in the United States, for help in treating the wounded. In October and December of 1944 the committee sent assorted medical and surgical supplies and 50,000 vitamins to Ste. Anne's, and in February of this year an ambulance. Mrs. Huttleston Rogers, executive chairman of the Medical and Surgical Relief Committee of America, reported that contributions for the month of April to Italy, India, China, Africa, France, Bolivia and the United States brought the total value of donated medicines and drugs to $714,290.71. Through its ability to assemble medical materials quickly and because of its stock of used instruments (often unobtainable new) the committee has been the means of bringing relief at crucial times to our own service, to allied fighting forces, to hospitals and to welfare agencies and to missions.

ORGANIZATION SECTION

Postwar Medical Service

THE JOINT COMMITTEE ON POSTWAR MEDICAL SERVICE

Meeting of March 17, 1945

The meeting of the Joint Committee on Postwar Medical Service was called to order by the Chairman, Dr. Ernest E. Irons, in the Board of Trustees Room of the American Medical Association Building, Chicago.

There were present, as members of the committee of the American Medical Association, Drs. E. L. Henderson, H. H. Shoulders, Olin West and Morris Fishbein; as members of the committee of the American College of Physicians, Drs. Ernest E. Irons and W. W. Herrick; as members of the committee of the American College of Surgeons, Drs. Frederick A. Coller, Evarts A. Graham, James M. Mason and Irvin Abell and, representing the organizations named, Federation of State Medical Boards, Dr. Walter L. Bierring; American Hospital Association, Mr. Graham L. Davis; Veterans Administration, Col. Hugo Mella; Liaison Office, Lieut. Col. Robert D. Bickel; Association of American Medical Colleges, Dr. Fred C. Zapffe; Catholic Hospital Association, Rev. A. M. Schwitalla, S.J.; Advisory Board for Medical Specialties, Dr. Paul C. Bucy; American Dental Association, Dr. Lon W. Morrey; U. S. Public Health Service, Col. F. V. Meriwether; Office of the Surgeon General, War Department, Col. F. M. Fitts, Lieut. Col. G. R. Gessner, Lieut. Col. H. C. Lueth and Col. G. M. Powell. Also present were Dr. Herman L. Kretschmer, President of the American Medical Association; Dr. R. L. Sensenich, member of the Board of Trustees of the American Medical Association, and Dr. Victor Johnson, Secretary of the Council on Medical Education and Hospitals.

Approval of Minutes of Meeting of Feb. 10, 1945.—The Chairman stated that changes in the circulated minutes suggested by Lieut. Col. Gessner, Father Schwitalla, Mr. Davis and Colonel Mella had been made and were incorporated in the minutes as published in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for March 17. The minutes as circulated, with the changes mentioned by the Chairman, were approved.

Committee Membership.—It was announced by the Chairman that Mr. Barry C. Smith, general director of the Commonwealth Fund, New York, had been appointed to serve as a member of the Joint Committee representing the American Medical Association and had accepted the appointment; that Dr. W. W. Herrick of New York had accepted appointment to represent the American College of Physicians in place of Dr. W. W. Palmer, resigned, and that Dr. B. R. Kirklin of Rochester, Minn., would represent the Advisory Board for Medical Specialties.

The Chairman introduced Dr. Paul C. Bucy, representing the Advisory Board for Medical Specialties in the absence of Dr. Kirklin, and Dr. Lon W. Morrey, representing the American Dental Association in the absence of Dr. C. W. Camalier.

Further Progress Report on Questionnaires Sent to Medical Officers.—Lieutenant Colonel Lueth presented an informative report concerning industrial medical practice and the economic aspects of postwar practice, covering the second two parts of the complete analysis of the postwar planning questionnaires that had been returned by medical officers. (The report presented by Dr. Lueth at the meeting of the Joint Committee on Feb. 10, 1945, covered the first two parts of the complete analysis and appeared in THE JOURNAL for March 31, 1945.) Following is a summary of the present report:

INDUSTRIAL MEDICAL PRACTICE

In the pilot questionnaire sent to 3,000 medical officers by the Committee on Postwar Medical Service, a number of questions concerning industrial medical practice were included. In the response only a small number of men indicated interest in this field, and the section on industrial practice in the final questionnaire was limited.

One fourth, 4,215, of all medical officers who returned the questionnaire indicated that they were interested in the industrial field, 863 men wanted full time positions. Requests for full time positions were scattered among the different graduation groups. Of the medical officers who would like to have full time positions in industrial medicine 56 per cent, or 484, indicated a desire to have special training to qualify for such positions, 44 per cent, 379, did not wish special training. The greatest number of requests for special training came from the most recent graduates.

About four times as many men wanted part time positions in industrial medicine as wanted full time positions. A little more than one third of those who would like to engage in part time industrial practice would also like to take special training. Special courses in industrial medicine were requested by 1,809 medical officers, including men who desired full time and part time positions and men who were undecided about future positions in industrial medicine.

In addition to the answers obtained from the section of the questionnaire specifically devoted to industrial medical practice, replies to questions on educational training indicated that 34 men wanted training in industrial medicine, 21 wishing short courses and 13 longer courses. Nearly all of the 13 who wished longer courses graduated before 1934, and about half of them were in industrial practice before entering military service.

A total of 4,215 medical officers expressed a desire to engage in industrial medical practice. About 80 per cent, 16,579, definitely indicated that they were not interested in this branch of medicine. The study revealed that the major fields of interest were industrial surgery, insurance and plant medical department work. It appears that those interested in furthering sound industrial medical practice in the future should seek to interest and encourage the younger men.

ECONOMIC ASPECTS OF POSTWAR PRACTICE

Economic aspects of future medical practice were indicated by the desires expressed by medical officers in 21,029 returned questionnaires analyzed.

The questionnaires were first studied for indications of the type and location of former medical practice, and it was found that 27.4 per cent, 5,785 medical officers, were formerly in general practice and 34.5 per cent, 7,282, had been in special practice. More than one third of the group studied, 7,962, gave no indication of their former type of practice or had not been in civilian practice before entering the armed forces. The total number of those who came directly from internships or residencies was 6,831.

Of the men formerly in general practice, 624 were from communities of less than 2,500 population, 1,962 from towns of between 2,500 and 25,000, 1,509 from cities of from 25,000 to 250,000 and 1,592 from the large cities of over 250,000 population. Only 61 of the 7,282 medical officers who were formerly in special practice came from communities of less than 2,500, and 791 from communities of between 2,500 and 25,000. More than three fourths of the specialists came from large cities, 2,500 from cities of 25,000 to 250,000 and 3,246 from cities of more than 250,000. Many, both general practitioners and specialists, did not indicate the size of their former locations. Among the specialists, about 40 per cent had been certified by the American specialty boards. Four fifths of the certified specialists had been graduated prior to 1935.

An analysis of the desires of medical officers to engage in private practice showed an increased interest in special types of practice. Of the 5,785 men who came from general practice, 4,326 indicated a desire to return to it. There were 3,530 medical officers who wanted to engage solely in general practice. Only 158 desired to return to communities of less than 2,500 population, compared to 625 who came from places of that size. About half as many wanted to return to communities of 2,500 to 25,000 and of 25,000 to 250,000 as originally came from them. Relatively few, 315, wanted to engage in general medical practice in cities of more than 250,000, compared to 1,592 who were formerly located in such cities. More than half, 418, of the 796 medical officers who indicated a desire to engage in general medical practice combined with part time teaching would like to practice in communities of more than 25,000 population.

Nearly two thirds of all medical officers in the group studied, 12,627, were interested in future specialty practice. Of these, about one half desired to engage solely in special practice and the other half in special practice combined with part time teaching. The whole group represents about half again as many as originally were engaged in special fields. Those interested in future specialty practice seemed to favor communities of 25,000 to 250,000 population.

One of the queries included in the questionnaire was "What is the minimum salary you would accept on a salary basis?" Only about half, 9,683, of the group studied replied to this question. There was a wide range in the answers, but the median appeared to be about $500 a month.

Four questions asked of the medical officers concerned voluntary redistribution to areas needing physicians. About 13 per cent, 2,817, stated that they would be willing to go to such an area if an office was already established, 11 per cent, 2,364, would go if a subsidy was provided for several months, more than 15 per cent, 3,284, would be willing to move if diagnostic facilities were available, and nearly 29 per cent, 6,091, would go if there were hospital facilities. From a study of the graduation groups involved, it appears that the younger men are willing to move into communities needing physicians, under certain preferred conditions, and that the majority of the graduates of 1937 or earlier are not willing to accept relocation.

The question of full time government service as a future type of medical practice was included in the questionnaire. About 85 per cent

of the medical officers indicated that they did not desire to remain in government service. Only 2,501 medical officers stated that they would like to stay in government service. Officers of the regular medical departments of the Army and Navy and other government services were considered separately in the study. Of this group of 532, 49 were older men who presumably wished to be retired after the war.

After extended discussion, the progress report was received and publication authorized.

Further Progress Report on Educational Internship and Residency Opportunities for Medical Officers.—Dr. Victor Johnson informed the Committee that he and Lieutenant Colonel Bickel were working out a plan whereby there will be available through the Bureau of Information at American Medical Association Headquarters as complete information as possible concerning openings in hospitals for internship and residency training. Requests for such information are already being received from returned medical officers, and it is expected that the machinery for providing it will be running smoothly in a very short time.

Dr. Graham thought that the number estimated by Dr. Johnson, 12,500, as desiring residencies probably was greater than would actually be the case, and Dr. Johnson agreed that probably the 12,500 or more men who had said that they wanted six months or more of hospital training would not all carry through on their desires, but he thought that it was better to be prepared for too many rather than for too few.

There was a lengthy discussion by most of those present, and it seemed to be the consensus that the most pressing single problem is the supply of physicians three years from now.

Dr. Johnson stated that his report will be ready for publication shortly, and the Committee authorized such publication.

Bureau of Information.—Lieutenant Colonel Bickel gave a brief report on the work of the Bureau of Information, stating that excellent cooperation was being had from the state medical societies, a follow-up system is being established, 65 requests for specific information as to places where men can practice have already been received, and the material for supplying answers to such requests is being gathered from the Procurement and Assignment Service, the U. S. Public Health Service and other agencies. To give the Committee an idea of what the men want to know, Dr. Bickel read one or two letters received from medical officers.

The Chairman stated that the report showed definite progress and growth and that one of the most important features of this bureau should be complete cooperation with the state organizations.

Local Organization of Courses for Graduate Study.—Dr. Johnson stated that the Council on Medical Education and Hospitals collects information semiannually from all kinds of organizations regarding short courses and publishes it semiannually, and that from now on the Council will ask for information concerning possible expansion.

Report of Subcommittee to Draw Up Recommendations to the Governors of the States (Dr. Shoulders, Chairman; Dr. Paullin, Dr. Coller, Father Schwitalla and, as consultants, Lieutenant Colonel Lueth and Miss Switzer).—Dr. Shoulders, chairman of the subcommittee, stated that his committee had been very active and that specimen letters designed to be sent to the governors of the several states had been drafted.

Following intensive discussion of all phases of the proposals offered, it was moved that a letter harmonizing the various drafts read be sent in the name of the Joint Committee directly to the governors of the states and that copies of it be sent to all agencies in the states that should be concerned in the matter. An amendment was offered that the subcommittee be empowered to take the necessary steps for the development of committees within the states for the purpose of advising the governors, and the Committee took action as follows: That a letter along the lines outlined by Dr. Shoulders, with certain modifications, be sent to the governor of each state and, in addition, that the subcommittee be empowered to take additional measures to see that those in authority in the states are apprised that these letters have been sent and to suggest measures for the development of advisory committees.

The Committee then adopted a motion that the proposed letter be given adequate publication, including publication in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, as a part of the minutes of the Joint Committee after the letters had been sent to the governors.

The letter as finally prepared, approved by the subcommittee and sent to the governor of each state, territory and the District of Columbia is as follows:

April 17, 1945.

The Honorable————
Governor of————
————
Dear Governor————

The undersigned Committee on Postwar Medical Service, composed of representatives from the several organizations mentioned, was created two years ago for the purpose of giving consideration to many medical problems which will arise as a result of the war and the demobilization which will follow.

Of particular interest to the Committee at the moment are the provisions of Public Law 346, 78th Congress (The G. I. Bill of Rights) as they may affect the entire field of medical education.

The governor of each state, as you doubtless are aware, is vested with the power and duty of certifying to the Veterans Administration the institutions in his state which are qualified to give acceptable courses of education and training in each of many categories.

The field of medical education, in its broadest sense, embraces (*a*) premedical education, (*b*) undergraduate education, (*c*) postgraduate education, (*d*) nursing education and (*e*) the education of medical technicians. There have been developed high standards of premedical education as well as undergraduate medical education. Medical schools are classified according to those standards. Similarly, there are well recognized standards in dental education and in nursing education. There should be little difficulty, therefore, in reaching decisions concerning institutions giving instruction in these fields.

This is true to a lesser extent with respect to the postgraduate education and training doctors receive in hospitals and with respect to schools for the education and training of medical technicians. It is true that many hospitals have been approved for intern and resident training and for the training of medical technicians in some fields. This approval is based on the number of beds and other facilities available in a hospital for teaching and the type of educational program carried on by the staff of the institution.

The importance of maintaining educational standards which are commensurate with the progress that has been made in the fields of medicine, dentistry and nursing must be obvious to you. The maintenance of these standards is in the public interest because they determine the quality of medical, dental and nursing care the public will receive.

It seems appropriate to suggest to you that certain schools which have thus far failed to secure approval will make effort to participate in the tuition payments under the G. I. Bill of Rights by having their names placed on the list of approved institutions which the governor will send to the Administrator of Veterans' Affairs. Such schools may be schools of the medical cults. These should be approved only after they thoroughly establish their ability to give a creditable course in the several subjects embraced in the basic sciences which are mentioned in the basic science laws in effect in most states.

The Committee on Postwar Medical Service is keenly aware of the difficulties which will face the governor in the administration of this act. We are aware also of the pressure which will be brought to bear on you to obtain your approval of institutions which are not qualified and equipped to give acceptable courses of education and training in these several fields.

The Committee, therefore, begs leave to recommend that the governor appoint an advisory committee composed of persons qualified to advise him with respect to the quality of education and training given by institutions in his state in the fields of medicine, dentistry, nursing and medical technology, which includes x-ray technicians as well as laboratory technicians.

The Committee wishes to assure the governor that the facilities and information in the hands of the Committee on Postwar Medial Service are available to him for whatever purpose he may wish to use them, and that we shall be glad to cooperate with him to whatever extent he may wish in the solution of these difficult problems.

Very respectfully yours,
COMMITTEE ON POSTWAR MEDICAL SERVICE
ERNEST E. IRONS, M.D., Chairman.
H. H. SHOULDERS, M.D., Secretary.

[List of Committee Members.]

Progress Report of Subcommittee on Surplus Medical and Hospital Supplies (Father Schwitalla, Chairman; Dr. Irons, Dr. Fishbein, Miss Switzer, Dr. Piersol).—Father Schwitalla presented a progress report, which he stated all the members of his subcommittee had seen but had not had opportunity to approve.

After discussion, the report of the subcommittee was received and filed, and consideration of the recommendations made therein tabled until the next meeting of the Joint Committee. The Chairman stated that the subcommittee would be continued to make a further report at the next meeting.

Further Progress Report on Laws Concerning Temporary Licensure.—Dr. Bierring informed the Committee that the Federation of State Medical Boards had held a meeting of

delegates on February 12 and 13, at which twenty-nine of the forty-four state boards were represented. Two definite actions were taken, one of which was to endorse the action of the Council on Medical Education and Hospitals recommending that the appointment of residents and house officers in approved hospitals be made only from graduates of approved medical schools. The second action had to do with temporary licensure: It was the opinion of the federation delegates that no definite action should be taken as regards any recommendation to state boards, that each individual board is responsible for determination or action. Dr. Bierring said it was the general feeling that temporary action was not the solution and that permanent licensure would be better. There is an altogether sympathetic attitude on the part of state board officers with respect to discharged medical officers. Some states have already acted, and others are sympathetic to permitting licensure for those graduates of approved schools returning from military service by exempting them from examination or giving credit for experience gained in military service. He thought that the individual state boards could be depended on to be very considerate in endeavoring to harmonize existing regulations for the benefit of those who desire to relocate.

Formulation of Lists of Medical Officers to Be Considered for Demobilization.—The Chairman brought up the matter of the formulation and submission of lists of medical officers needed in essential civilian positions who might be considered for demobilization.

Dr. Zapffe stated that the Association of American Medical Colleges has submitted a list of essential teachers to the Procurement and Assignment Service but that, so far as he knows, no action has been taken by the Army or Navy. Lieutenant Colonel Lueth thought the Joint Committee should figure out a "civilian adjusted service rating" card for the purposes involved. On motion of Dr. Henderson, duly seconded and carried, the Chairman appointed the following subcommittee to study the problem and bring recommendations to the Joint Committee: Dr. Frederick A. Coller, Chairman; Dr. Victor Johnson, Dr. H. H. Shoulders, Lieut. Col. H. C. Lueth, Dr. Fred C. Zapffe, Dr. Walter L. Bierring, Dr. W. W. Herrick and Rev. A. M. Schwitalla.

Report of Subcommittee on Establishment of Medical Corps in the Veterans Administration.—Father Schwitalla, chairman of the subcommittee, presented the following report, stating that the action called for is a decision by the Joint Committee as to whether or not the subcommittee should interest itself in supporting one or the other of the bills mentioned in the report, whichever is recognized as the more desirable:

This subcommittee was created by the Committee on Postwar Medical Service in response to the suggestion expressed by some Committee members that some of the criticisms leveled by professional persons and the public against the quality of medical care given to our veterans under the present form of organization of the medical service in the Veterans Administration are possibly justified. The subcommittee as such is not concerned with the validity of the criticism but is concerned with the important suggestion that there should be in the Veterans Administration for the effective medical care of the veterans, by reason of the enormous size of the problem as well as for many other reasons, a medical corps comparable in standards, quality and numerical strength of the personnel and procedures to the Medical Corps in the Army, the Navy and the Public Health Service.

Two bills dealing with a reorganization of the medical service in the Veterans Administration have been introduced into the House of Representatives since the opening of the 79th Congress, first session, and have now been referred to the Committee on World War Veterans Legislation: H. R. 1661, introduced Jan. 22, 1945 by Mrs. Edith Nourse Rogers, Republican of Massachusetts, and H. R. 2253, introduced Feb. 19, 1945 by Mr. J. Percy Priest, Democrat of Tennessee.

THE ROGERS BILL, H. R. 1661

The purpose of the Rogers bill is "to authorize the establishment of a permanent veterans' medical and hospital service in the Veterans Administration, and for other purposes." The bill establishes the Medical and Hospital Corps (section 2 correction to be introduced), which includes the following corps: (1) Medical, (2) Nurse, (3) Laboratory Technicians, (4) Pharmacists, (5) Dietitians, (6) Social Work. It has been recommended by interested groups that there be also (7) a Dental Corps, (8) a Therapists in Physical Medicine Corps and (9) a Librarians' Corps. The functions of these various corps are suggested by their names and are to be more fully defined by the administrator. Clarifications in the bill are to be introduced here since, among other defects in this section, there seems to be some confusion in the designation of the various corps.

The bill goes on to define the Medical Corps, stating the membership of the various corps, sections 4 to 11 inclusive. (In section 7 there is mention for the first time of a Corps of Physical Therapists and Occupational Therapists.) Corrections must be introduced into sections 4, 5, 6, 7 and 11 to harmonize them with prevailing practice as well as to bring unity into the organization.

The successive sections, beginning with section 12, deal respectively with the appointment of the Surgeon General of the Veterans Administration and of the various heads of the several corps (section 12), filling of vacancies (section 13), requirements for promotion (section 14), power vested in the Surgeon General to prescribe rules and regulations (section 15), establishment of the Reserve Corps and its regulations (section 16), powers of a discipline board (section 17), interchangeability of officer personnel with the Army or the Navy (section 18), establishment of a professional medical council (section 19), authorization of expenses (section 20), authority for leaves (section 21), employment of civilian professional personnel (section 22), insignia (section 23), definitions particularly of military benefits (section 24), subjection of the corps to articles of war and exemption from Selective Service (section 24, c, d), commissioned officers and men of the corps entitled to benefits under U. S. Employees' Compensation Act (section 25), pay and allowances (section 26) and "conflict of law" clause (section 27).

COMMENT ON THE ROGERS BILL

The bill as presented by Mrs. Rogers seems in many respects excellent and meets the purposes which those have in mind who have pleaded for the establishment of a Medical Corps in the Veterans Administration. Some persons will, no doubt, say that the bill establishes too complex an organization, but when it is borne in mind that the organization is designed to take care of by far the largest group of persons for whom the government is directly responsible, it would seem that the type of organization contemplated in H. R. 1661 is by no means too intricate. The interim report of the Subcommittee on Wartime Health and Education, February 1945, shows abundantly how large is the responsibility of the government for the health needs of the veterans.

Some of the corrections in the bill besides those to which attention has already been called might be stated to be the following: The power of the Surgeon General to employ civilian technical personnel should be wider than it is now contemplated in the bill (section 22); equivalence for credit for time service in the various government agencies should be liberalized (section 26 a, 1); disability provisions should probably be extended (section 26 a, 2); certain Civil Service deductions had probably better be omitted (section 26 a, 3); other provisions of the bill with reference to pay, for example, exemption of retirement pay from taxation, will probably merit careful restudy (section 26 in toto) and possibly radical reformulation or deletion. Perhaps these "benefits" are not the concern of this subcommittee.

THE PRIEST BILL, H. R. 2253

The purpose of the Priest bill is stated to be "to establish in the Veterans Administration a commissioned service consisting of physicians, surgeons, dietitians, nurses and medical technicians."

Section 1 establishes the Veterans Administration Medical Service in the Veterans Administration to perform the functions and duties now being performed by civilian physicians, surgeons, dentists, dietitians, nurses and medical technicians. Section 2 defines the commissioned personnel, section 3 the medical director and deputy medical director, section 4 the grades, ranks and titles. Section 5 prescribes the method of appointment of commissioned personnel in both the regular and the reserve corps. Section 6 provides for pay and allowances for the different classes of officers and enlisted personnel, while section 7 provides for promotions and the separation of commissioned officers from the regular corps. Provision is made in section 8 for the retirement of commissioned officers, and in section 9 military benefits are defined. Section 10 authorizes an allowance for uniform and equipment for each commissioned officer. Interchangeability of personnel with the Army, Navy or Coast Guard is legalized in section 11. The power to write regulations is vested in the medical director, subject to the approval of higher authorities, section 12. Section 13 provides for the use of the service in war emergency, and finally section 14 authorizes appropriations made to the Veterans Administration under "salaries and expenses" to be available to the personnel authorized by this act.

RECOMMENDATIONS

In view of the fact that at present these two bills are before committees of the House of Representatives, the subcommittee recommends to the Committee on Postwar Medical Service:

1. That the subcommittee be asked to submit the bills to further study with the intention of ascertaining the suitability of the bills for meeting (*a*) the needs of the veterans for a comprehensive medical and hospital service of a high order of excellence; (*b*) the needs of the Veterans Administration for a flexible, effective and professionally superior organization in the health care of the veterans; (*c*) the needs of the various professional groups in medicine and its related professions for an efficient organizational instrument within the Veterans Administration for channeling to the veterans the very best care which the various professions have to offer.

2. That the subcommittee give discriminating study to the two bills with the purpose of determining which of the two can better meet the purposes which the Committee on Postwar Medical Service has in mind.

3. That the subcommittee be requested to ascertain the responsible agencies which will carry through the bills pertaining to the health care of veterans from their present legislative status to final passage; to ascertain, furthermore, how the Committee on Postwar Medical Service can be of assistance in facilitating the passage of the bill and to determine in whose hands the leadership for sponsoring these bills should be centralized so as to avoid conflicting activities.

4. That the subcommittee determine to what extent the summary of recommendations of Report No. 4 of the Subcommittee on Wartime Health and Education is achievable more effectively through the development of a medical corps and auxiliary corps as contemplated in these bills.

5. That the subcommittee be authorized to enlarge its membership if such enlargement may seem desirable, depending on the interest which the Committee decides to take in furthering the passage of the bill.

ALPHONSE M. SCHWITALLA, S.J., Chairman.
LEROY H. SLOAN.
H. H. SHOULDERS.

After lengthy discussion, the Committee endorsed the intent and provisions of the Rogers Bill, H. R. 1661, with modifications that are quite generally recognized as necessary and that have already been submitted, and the subcommittee was continued and instructed to report further at the next meeting.

Report of Subcommittee on Enrolment of Medical Students.—The report of the Subcommittee on Enrolment of Medical Students was presented by Lieutenant Colonel Lueth. (This report was printed in THE JOURNAL, April 7, p. 931.)

Dr. Johnson presented each member of the Committee with a statement which he and Dr. Zapffe had prepared in anticipation of hearings to be held on the Ellender bill, S. 637. Dr. Zapffe commented on some portions of the statement presented by Dr. Johnson, saying that the emergency is acute; the medical schools are concerned about the output of physicians; as the outlook is now, there will be very few graduates in 1949 and in 1950 there probably will be none; out of every entering class 20 to 25 per cent do not graduate; if no students are available for 1946, it is essential that something be done; in the main, the Ellender bill should be supported in principle and everything possible done to secure its passage.

Colonel Fitts presented figures showing the estimated number of graduates in medicine for the years 1945 through 1949 under Army and Navy specialized training programs. He stated that while the Navy is putting some men into first year classes in 1946 the Army is not, which means that the graduates in medicine in 1950 will be limited to women, 4-F's and veterans.

It was stated by Dr. Zapffe that the Association of American Medical Colleges had gone into this matter with the Veterans Administration. The Committee concluded that there would be hardly any of the now returning men available to the medical colleges, so that only two groups could be counted on—the women and the 4-F's.

The report of the subcommittee presented by Lieutenant Colonel Lueth, recommending support of the Ellender bill, was approved.

Additional Member of Subcommittee on Enrolment of Medical Students.—Pursuant to remarks by Lieutenant Colonel Lueth, the Chairman appointed Dr. Fred C. Zapffe as a member of the Subcommittee on Enrolment of Medical Students.

Letters from Medical Officers.—The Chairman presented for the interest of the Committee a letter from an overseas medical officer, and Colonel Powell informed the Committee that it has been learned informally that the European theater plans to carry out a program of professional rehabilitation for medical officers as far as time and other conditions permit.

Informational Reports.—Office of the Surgeon General, War Department: Lieut. Col. G. R. Gessner stated that the Army Air Forces has instituted a clinical refresher training program for its medical officers similar to the Army program; it provides two weeks of didactic work and ten weeks of hospital work. (An account of this activity appeared in THE JOURNAL for April 7, 1945.)

American Dental Association: Dr. Morrey presented a report of the War Service and Postwar Planning Committee of the American Dental Association in accordance with the request of Dr. C. W. Camalier. (This report was also presented to the Committee on Feb. 10, 1945.)

Liaison Office: Lieutenant Colonel Bickel reported that the project of replying to medical officers who submitted questions on their returned Postwar Planning Questionnaires has been completed for the first 23,000 questionnaires, and each officer submitting such questions has been sent a personal reply in the name of the Committee on Postwar Medical Service. Questions dealing with policies of this committee were referred to Dr. Irons for reply; questions concerning policies of the American Medical Association were referred to Dr. West; questions about medical education were referred to Dr. Johnson and Dr. Arestad, and questions concerning licensure, reciprocity and other legal matters were referred to Mr. J. W. Holloway Jr. for information on which to base replies. All other inquiries were answered directly. There were about 200 such replies sent out, and the work of answering the questions of medical officers is now current. As new inquiries come in they will be answered immediately.

Time and Place of Next Meeting.—The Committee voted to hold its next meeting at the American Medical Association Headquarters in Chicago on Saturday, May 12, 1945.

The meeting adjourned at 1:50 p. m.

H. H. SHOULDERS, M.D., Secretary.

Bureau of Information

KANSAS REPORTS

Mr. Oliver E. Ebel, executive secretary of the Kansas State Medical Society, has recently sent the Bureau of Information valuable data concerning some of the counties in Kansas. These reports contain unusually concise and descriptive remarks about the general characteristics of the counties and of the present needs of these areas for physicians.

The accompanying table gives certain of the economic data for ten representative counties chosen from various sections of the state.

Kansas

County [1]	Principal Cities [2]	Population	Physicians Under 65	Persons per Physician	Persons per Telephone [3]
Doniphan	.....	10,408	4	2,602	6
Ellis	Hays	16,034 6,385	12	1,336	10
Graham	.....	4,404	0	.....	12
Johnson	Olathe	40,229 3,979	4	10,057	7
McPherson	McPherson	22,904 7,194	6	3,817	5
Ness	.....	6,395	1	6,395	7
Saline	Salina	32,974 21,073	17	1,940	6
Sedgwick	Wichita	194,945 114,966	113	1,725	7
Shawnee	Topeka	84,765 67,833	40	2,119	5
Wyandotte	Kansas City	144,453 121,458	63	2,293	9

1. Bureau of census, estimated population 1943.
2. Bureau of census, population 1940.
3. Based on 1940 figures, American Telephone and Telegraph Company.

Excerpts from the remarks contained on the county summary sheets follow:

Doniphan.—Doniphan County is in the northeast corner of the state. It is an apple growing area without large cities and with almost no other industry. The county is separated from St. Joseph, Mo., by the Missouri River and is near Kansas City.

Ellis.—Ellis County is located in the center of the western third of the state and has splendid medical facilities. These furnish medical and hospital care for a large portion of the western part of the state. Hays, on the eastern boundary of this area, is considered the most lacking in medical care. The comparatively high ratio of physicians here must be considered in respect to the wide area outside the county served by doctors.

Graham.—Graham County, north and west of Ellis County, represents a typical county in the western part of the state.

Johnson.—The close proximity of this county to Kansas City decreases the need for doctors in spite of a high physician-population ratio.

McPherson.—This county is an agricultural and oil producing district near the center of the state and includes a number of small towns. At the present time medical care is given by physicians who would be retired had the war not happened.

Ness.—This is an agricultural community. At the present time there is only one doctor.

Saline.—This county, like Ellis County, is considered a medical center. It serves an area east of Ellis County.

Sedgwick.—This, the second largest county in Kansas, has experienced a large wartime increase in population owing to the presence of several airplane factories and other war industries. This county is a business and medical center for the south central part of this state. It is locally estimated that the population is now 50,000 more than shown by the 1943 census figures.

Shawnee.—This county is the third most populous county in Kansas. It contains the state capital and many state operated institutions and medical facilities. Since many physicians in this county have full time appointments in various institutions or in the state board of health, the ratio of practicing physicians to population is higher than the table indicates.

Wyandotte.—This county is similar to Sedgwick County in many respects. Kansas City, Mo., is just across the river from Kansas City, Kan., and this factor influences the medical economic aspects of the area.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. The further investigation through state and county medical societies is thus greatly facilitated, and much unnecessary correspondence and perhaps travel may be avoided. In many communities vacancies are being held open for physicians now in the medical service. The number of physicians listed may therefore be misleading and consequently direct correspondence with the county medical society will always be necessary.

Washington Letter

(From a Special Correspondent)

May 7, 1945.

V Day Not to End War for Army Doctors

Final victory on both fronts will not mean the end of the war for the physicians and surgeons of the Army Medical Department, Major Gen. George F. Lull, Deputy Surgeon General, told the Columbia University College of Physicians and Surgeons. With battle casualties returning at 30,000 to 40,000 a month, the department will be busy providing these men with medical and surgical care. General Lull says that many medical officers will be needed long after fighting stops. Long term cases will require considerable reconstructive surgery and will not reach the stage of maximum improvement until long after V day. The number of casualties is large in comparison with the number of skilled medical specialists, and it has been expedient to concentrate certain specialties in a relatively small number of hospitals, he explained. Special treatment centers have been established in a number of general hospitals in this country, covering one or more of the following specialties: amputation, neurosurgery, thoracic surgery, tropical diseases, surgery of blood vessels, neuropsychiatry, plastic surgery, care of the deaf and care of the blind.

Nurses Not to Be Drafted in This War

Major Gen. Norman T. Kirk, Surgeon General, states that although he still believes passage of the nurse draft bill is "absolutely necessary," it is unlikely that any American nurse will be drafted in this war. The measure requested by President Roosevelt January 6 passed the House March 7 and was approved by the Senate Military Affairs Committee March 28 but is being allowed to die on the Senate calendar. Representative Frances P. Bolton, Republican of Ohio, has told the senators that a nurse draft "would be unwise." Senator Edwin C. Johnson, Democrat of Colorado, and Senator Robert A. Taft, Republican of Ohio, promised to oppose the measure on the Hill if introduced and acting majority leader Lister Hill, Democrat of Alabama, has decided against calling it up.

National Induction of Cadet Nurses May 12

National induction ceremonies of the U. S. Cadet Nurse corps will be held Saturday, May 12, in cities and communities throughout the country, reports Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service. Extensive ceremonies will take place simultaneously with a coast to coast program from New York City. Dr. Parran will administer the formal induction pledge to nurses gathered at public ceremonies all over the nation. More than 60,000 new students enrolled since last year will take the formal pledge for the first time. Miss Lucile Petry, corps director, will pay special tribute to the cadet nurses.

Final Senate Approval for Hospital Bill Forecast

Despite a hitch in authorization of the Tydings-Bilbo bill for a 1,500 bed hospital center in Washington after the war, its sponsors expect final Senate approval. Senator Ellender, Democrat of Louisiana, has asked for reconsideration of passage of the bill voted last week by the Senate.

Capital Notes

The District of Columbia Social Hygiene Society has passed resolutions describing current District health regulations as too indefinite and ineffective for vigorous enforcement of venereal disease control measures and opposing H. R. 2424, a bill to create a quasiautonymous tuberculosis organization to supplant the present Tuberculosis Bureau of the District Health Department.

Chairman Basil O'Connor of the American Red Cross Society has thanked the nation for its oversubscription of the 1945 Red Cross War fund goal of $200,000,000. He reported that a total of $219,075,000 was contributed. He also announced that scores of trained disaster workers, including doctors and nurses, had been sent into tornado and flood areas of eastern Oklahoma, Kansas and Arkansas.

A rabies control bill for the District of Columbia is reported held up in the Budget Bureau awaiting the approval of Surg. Gen. Thomas Parran of the U. S. Public Health Service.

Corporation Counsel Richmond B. Keech opines that unless Congress enacts a law specifically authorizing the sterilization of feebleminded women no further operations of this kind can be performed in the District of Columbia.

To assure an adequate supply of amyl acetate, made from amyl alcohol, for the production of penicillin, the WPB announces that amyl alcohol and amyl acetate have been placed under allocation control.

Official Notes

DOCTORS LOOK AHEAD ON NATIONAL HOSPITAL DAY

Once in a long time a combination of occasions offers opportunity for a special broadcast in such a series as Doctors Look Ahead. On May 12 there occurs National Hospital Day and the fiftieth anniversary of the Chicago Lying-In Hospital. On this occasion the entire production facilities of the National Broadcasting Company needed for Doctors Look Ahead will be moved to the Dora De Lee Amphitheater at the Chicago Lying-In Hospital, and the program will be devoted to a history of the hospital and of the late Dr. Joseph B. De Lee —two stories which are inseparable and which typify the pioneer spirit behind the growth of American medicine. In broadcasting on this occasion the medical profession salutes not only this hospital and this doctor but all institutions and all doctors of similar type which exemplify American medicine at its best—free, daring, yet solidly scientific and constructively conservative.

In addition to the May 12 broadcast, The Beloved Pioneer, the following programs are scheduled:

May 19. Look Sharp.
May 26. Unfinished Business (Dr. Fishbein).

Doctors Look Ahead is heard on one hundred and twenty-three stations of the National Broadcasting Company network each Saturday at 4 p. m. Eastern War Time (3 p. m. Central War Time, 2 p. m. Mountain War Time and 1 p. m. Pacific War Time).

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARIZONA

The Medical Quarter Hour.—The Arizona State Medical Association on March 26 opened a second series of radio transcriptions during its "Medical Quarter Hour" Monday night at 6:15 over station KTAR. "More Life for You!" is the theme of this series of transcribed interviews and round table discussions. The first series was devoted to "American Medicine Serves the World at War" and consisted of a small group of radio transcriptions. "Keep Cool" will be the theme of a series of transcribed interviews with Dr. William W. Bauer, Director of the Bureau of Health Education, American Medical Association, June 25 through September 10. This activity on the part of the state association includes the advertisement of the program in various papers of the state and the distribution of pamphlets to patients of physicians. The council of the association has appropriated funds to continue these broadcasts for a year.

ARKANSAS

Personal.—Dr. S. J. McGraw has been appointed health officer of El Dorado.——Dr. Albert S. Buchanan, Prescott, has been appointed a member of the state board of health.——Dr. and Mrs. William C. Russwurm, Helena, celebrated their golden wedding anniversary on January 10.

Oldest County Society in State.—The Phillips County Medical Society, which is considered the oldest medical society in Arkansas, held its seventy-fourth annual meeting recently. Dr. Earl F. Norton, Marvell, was chosen president and Dr. James W. Nicholls, Helena, vice president. Dr. Montague Fink, Helena, is permanent secretary of the society. The society was organized in 1871 and antedates the establishment of the Arkansas Medical Society.

CALIFORNIA

University News.—Dr. Isabella H. Perry, assistant professor of pathology, University of California Medical School, San Francisco, was recently given the additional title of coordinator for cancer clinics.

Personal.—Dr. Jacob C. Geiger, director of public health of the city and county of San Francisco, recently received the European and Catholic Order, the Cavaleiro da Ordem de Cristo (Order of Christ), in recognition of his services to the Portuguese people of Portugal and California.

Changes in Health Officers.—Dr. Nicolai N. Rilcoff, formerly venereal disease control officer with the Kern County Health Department, has been appointed health officer of the county, succeeding Dr. John K. Coker Jr., Bakersfield, effective April 1.——Dr. John A. Carswell, Santa Barbara, has resigned as health officer of Santa Barbara County.

Conference on Health Professions.—On April 21 the Conference on Health Professions was held on the San Francisco campus of the University of California for high school and junior college counselors. Sponsored by the Northern California Vocational Guidance Association and the University of California, the conference featured talks on the professions of medicine and allied occupations, dentistry and related fields, pharmacy, nursing and public health nursing and public health occupations.

ILLINOIS

Personal.—George H. Van Dusen became superintendent of the Christian Welfare Hospital, East St. Louis, April 5.——Dr. Paul H. Pernworth, Venice, addressed the student branch of the American Pharmaceutical Association at the St. Louis College of Pharmacy, St. Louis, March 22, on "Practical Application of Certain Pharmaceutical Agents to Clinical Medicine and Surgery."——Dr. John H. Brantley, Poplar Grove, recently completed fifty years in the practice of medicine.

Outbreak of Food Poisoning.—About 100 persons were known to be ill in St. Francisville, March 26, in an outbreak of food poisoning that was subsequently attributed to long horn cheese which had been purchased from two local stores. In the subsequent investigation the cheese from the two stores was found to have been obtained from the same distributor in a nearby town in Indiana and the sale was stopped. Additional investigation traced the cheese to East St. Louis and then to a cheese manufacturing plant in northern Illinois. During the investigation it was revealed that similar outbreaks showing symptoms of diarrhea, nausea, vomiting and fever occurred in other sections of the country including one in Dyersburg, Tenn. All of the cheese that could be located was withdrawn from the market by the distributor.

Chicago

Personal.—Dr. Josiah J. Moore, Treasurer of the American Medical Association and president of the Chicago Medical Society, will receive the honorary degree of doctor of laws by Montana State University, Missoula, during its graduation exercises in June. The degree is being awarded to Dr. Moore, an alumnus of the university, for his "distinguished record in pathology." Dr. Moore will deliver the commencement address.

Rorschach Test Course.—Samuel J. Beck, Ph.D., head of the psychology laboratory, Michael Reese Hospital, will conduct the Rorschach test course at the hospital, June 4-8. The records to be demonstrated will be representative of the older adolescent and younger adult with special emphasis on persons discharged from military services. Persons interested may communicate with the secretary of the department of neuropsychiatry at the hospital.

Meeting of Council of Social Agencies.—The twelfth annual meeting of the health division of the Council of Social Agencies of Chicago will be held in the ballroom of the Standard Club, May 16. Among the speakers will be Drs. Robert S. Berghoff on "Tuberculosis Control in the State of Illinois including County of Cook," and Reginald M. Atwater, New York, "Realistic Planning for Community Health." Mr. Alexander Ropchan is executive secretary of the health division of the council.

MARYLAND

Society News.—Dr. Samuel A. Cosgrove, Jersey City, N. J., addressed the semiannual meeting of the Baltimore City Medical Society April 6 on "Conservatism in Operative Intervention in Obstetrics."

Personal.—Dr. Lawrence F. Woolley, formerly clinical director of the Sheppard and Enoch Pratt Hospital, Towson, has been appointed director of therapy and research at the Haarlem Lodge, Cantonsville, and Elkridge Farm, Ellicott City.

Bureau of Medical Services.—The state board of health has been authorized to create a bureau of medical services under the provisions of a law which is to become effective June 1. The bureau will administer a program furnishing medical care for indigent and medically indigent persons and will conduct and operate the chronic disease hospitals to be constructed in the postwar period. A chief of the bureau will be nominated under the merit system by the director of health. A council of medical care will be established by the state board to assist in formulating policies connected with the medical care program.

MICHIGAN

Changes in Health Officers.—Dr. Ralph Ten Have, Grand Haven, health officer of Ottawa County, has resigned to enter private practice.——Dr. D. H. Swengel recently resigned as health officer of the Cass County Health Unit to accept a similar position with the Mecosta-Osceola District health unit.

The Hickey Memorial Lecture.—Dr. John B. Barnwell, associate professor of internal medicine, University of Michigan Medical School, Ann Arbor, gave the ninth annual Hickey Memorial Lecture before the Wayne County Medical Society, Detroit, April 2. His subject was "Observation of the Minimal Lesion." The Hickey lectures commemorate the life and works of Dr. Preston M. Hickey, who was the first chief of the roentgen ray department at Harper Hospital and later professor of roentgenology at the University of Michigan Medical School, a position he held until his death, Oct. 30, 1930.

Mental Clinics for Veterans.—Five clinics for veterans have been established by the Michigan Society of Neurology and Psychiatry at Ann Arbor, Detroit, Flint, Kalamazoo and Saginaw in cooperation with the Michigan State Hospital Commission and the state office of veterans' affairs. The Detroit clinic began accepting patients for treatment February 6. This clinic, which is financed principally by the war chest of metropolitan Detroit, occupies quarters provided by Harper Hospital and is in operation three evenings each

week; eighteen psychiatrists are contributing their services without compensation. Five additional clinics in upper Michigan are being planned by the Michigan Society of Neurology and Psychiatry sometime within the near future.

Regional Meeting of Federation for Clinical Research.—The first regional meeting of the American Federation for Clinical Research was held at the Dr. William J. Seymour Hospital, Eloise, March 10, with Dr. Gordon B. Myers, professor of medicine, Wayne University College of Medicine, Detroit, acting as chairman. Among the speakers were:

Dr. Paul H. Noth, Detroit, Follow-Up Studies on Patients with Heart Wounds.
Dr. Jere M. Bauer, Ann Arbor, Vitamin D Intoxication with Metastatic Calcification, a Fatal Dose in an Adult.
Drs. Charley J. Smyth and Andrew G. Lasichak, Eloise, Influence of Amino Acids on Voluntary Food Intake.
Drs. Edwin T. Williams and Franklin H. Top, Detroit, Graphic Method for Rapid Estimation of Clinical Status in Poliomyelitis.
Dr. John H. Seabury, Ann Arbor, Recent Treatment of Subacute Bacterial Endocarditis.
Dr. Herman M. Pollard, Ann Arbor, Effects of Lipotrophic Substances in Biliary Disease.

Centennial Celebration of St. Mary's Hospital.—A two day program, May 16-17, will be held at St. Mary's Hospital, Detroit, to observe its 100th anniversary. Dr. Euclide V. Joinville, president of the hospital staff, will give the address of welcome at the clinical program the second day, to be held for physicians in the auditorium of Wayne University College of Medicine. Among the speakers will be:

Dr. William J. Stapleton Jr., Detroit, History of Wayne University College of Medicine—St. Mary's Hospital Association.
Dr. Russell L. F. Cecil, New York, Modern Conception of Arthritis and Its Management.
Dr. Emil Novak, Baltimore, Functional Tumors of the Ovary.
Dr. Alexander Brunschwig, Chicago, Extension of Radical Surgery in the Treatment of Advanced Abdominal Carcinoma.

Dr. Frederick A. Coller, Ann Arbor, will preside at a round table discussion on diseases of the gallbladder, participated in by Drs. Hugo A. Freund and Charles S. Kennedy, Detroit, in addition to the other guest speakers. Dr. Arturo Castiglioni, professor of the history of medicine, Yale University School of Medicine, New Haven, will be the guest speaker at the dinner meeting in the Statler Hotel in the evening.

Annual Alumni Clinic Day.—Wayne University College of Medicine Alumni Association will hold its annual alumni clinic day in the auditorium of the medical school in Detroit, May 16. Among the speakers will be:

Dr. Loren W. Shaffer, Detroit, Modern Treatment of Syphilis.
Arthur H. Smith, Ph.D., Detroit, Recent Advances in the Field of Nutrition.
Dr. Paul H. Noth, Detroit, Rheumatic Fever.
Dr. Amedo S. Marrazzi, Detroit, Intravenous Anesthesia.
Dr. Charles B. Huggins, Chicago, Endocrine Treatment of Carcinoma of the Prostate.
Dr. Geza de Takats, Chicago, Problem of Thromboembolism.
Dr. J. Grafton Love, Rochester, Minn., Protruded Intervertebral Disks.
Dr. Roscoe R. Graham, Toronto, Ont., Surgery of Peptic Ulcer.

A dinner session, with Dr. Clarence E. Umphrey, Detroit, acting as toastmaster, will be addressed by Dr. Irvin W. Sander, Detroit, who will be installed as president at the meeting, and Dr. Clarence A. Mills, professor of experimental medicine, University of Cincinnati College of Medicine, Cincinnati, on "Climatic Imprint on Man." A feature of the meeting will be the inauguration this year of honors to fifty year graduates. Because of the initiation this year the classes from 1881 to 1885 will be similarly honored.

NEW HAMPSHIRE

George Moulton Honored.—Plans are under way to hold a testimonial dinner at the Statler Hotel, Boston, May 17, to honor George A. Moulton, Phm.D., Peterborough, in recognition of his service to pharmacy. Any one wishing to participate in the memorial should communicate with Carleton A. Wheeler, Gray Rocks, Old Street Road, Peterborough.

NEW JERSEY

New Head of Tuberculosis Division.—Dr. Irving Willner, assistant physician in charge of the division of tuberculosis of the bureau of health, Newark Health Department, has been appointed director of the division, succeeding the late Dr. M. James Fine.

Postwar Expansion for Medical Center.—Plans to expand the facilities of the Jersey City Medical Center after the war to care for children in a "hospital school" while their mothers are undergoing treatment were announced by Mayor Frank Hague, April 24. No specific plans were given, but it was indicated that the proposed school would be staffed with "nurses, teachers and physicians who would supervise and teach the children with expert care while they are temporarily orphaned."

Ricketts Prize Awarded.—Maurice R. Hilleman, Ph.D., Brunswick Arms, New Brunswick, has been awarded the Howard Taylor Ricketts Prize by the University of Chicago. The presentation of the award took place on the thirty-fifth anniversary of the death of Dr. Howard Taylor Ricketts, who died of typhus May 3, 1910, while conducting research on the disease in Mexico. Dr. Hilleman was given the prize for developing a way of making an antiserum of value in identifying a recently discovered group of viral agents. The viruses which he studied cause diseases in both animals and man and include the agents of psittacosis, lymphogranuloma venereum and atypical types of pneumonia. His investigations resulted in the discovery of a more efficient tool for identifying the viruses of this group. Dr. Hilleman is now engaged in investigative work in the field of filtrable viruses with E. R. Squibb and Sons.

NEW YORK

Changes in State Society Officers.—At the April meeting of the council of the Medical Society of the State of New York, Dr. Herbert H. Bauckus, Buffalo, resigned to make it possible for the president-elect, Dr. Edward R. Cunniffe, New York, to take over the office at the same time he normally would have if the house of delegates had met in May. Dr. Cunniffe assumed the presidency May 1. Dr. Walter Guernsey Frey Jr., New York, has been elected to succeed Dr. George W. Kosmak, New York, who has been acting as assistant secretary during the past few months of emergency in the society and who also resigned at the April meeting.

Results of Service Questionnaires.—Of the physicians who on April 24 had returned questionnaires to the war participation committee of the Medical Society of the State of New York, 518 indicated that they want to practice in the same location from which they came when they leave military service. About half of the group replied that they wanted postgraduate refresher courses when they return. Of the total, 193 think they will want or need financial assistance to resume practice on their return. Forty-five of the approximately 710 questionnaires returned thus far replied that they planned to stay in government service of some kind. The questionnaire study is a part of the society's program to assist members returning as medical veterans.

Kaiser Medal Goes to Colonel Wentworth.—The Rochester Academy of Medicine has announced Col. Edward T. Wentworth, M. C., as the Albert David Kaiser medalist for 1945. The medal is awarded annually by the academy to honor one of its own members whose services have been considered outstanding. Colonel Wentworth was chosen in recognition of both his community service and the honors he has won in military duty. Colonel Wentworth, who graduated at Harvard Medical School, Boston, in 1913, served an internship and residency at the Rochester General Hospital. He has spent all of his time practicing in Rochester with the exception of service in the two world wars. He was credited with organizing base hospital 19 in World War I and also in World War II, a unit which he now heads somewhere in Europe. After the first world war he was a member of the medical reserve corps. Colonel Wentworth is past president of the Medical Society of the County of Monroe, the Rochester Academy of Medicine and the Rochester Pathological Society. The medal was presented to Colonel Wentworth in absentia and the citation was read by Dr. Walter S. Thomas, Rochester. Dr. Harold W. Brown, professor of tropical diseases, DeLamar Institute of Public Health, Columbia University College of Physicians and Surgeons, New York, gave an address on "Tropical Diseases, with Special Reference to Filariasis."

Millions Authorized for Veterans' Aid.—Governor Dewey on April 17 signed a bill appropriating $2,825,000 for the first year's operation of a statewide program to aid returning war veterans in rehabilitation and employment. The program, which includes the creation of a veterans' affairs division in the state executive department, will proceed after the governor names a state director, who must be a veteran. The new division will be empowered to establish rest camps and local veterans' service agencies as well as coordinate other veterans aid plans and expand "on-the-job" and apprentice training programs. The service agency will be set up in each county with state aid up to $5,000. Newspapers indicated that the agencies also may be organized in cities. On April 22 the governor signed a bill extending to all handicapped persons, irrespective of the type or nature of the cause of their handicap, the benefits of machinery already set up by the state for the treatment of the physically handicapped. In a comment to the press, the governor said that "what makes this

legislation particularly important is the effect it will have in providing additional procedure for the care and adjustment of the many veterans who will be returning after this war is over and who will be in need of such care and adjustment." The bill was developed by the temporary veterans commission and the state department of mental hygiene and specifically removes the exclusion of epileptics from the benefits of the statute.

New York City

The Bela Schick Lecture.—Dr Allan M Butler, associate professor of pediatrics, Harvard Medical School, Boston, delivered the third annual Bela Schick Lecture, April 20, under the auspices of Mount Sinai Hospital His subject was "Estimation and Parenteral Provision of Maintenance and Rehydration Requirements for Dehydrated Patients."

A Subcommittee on Industrial Medicine.—A Committee on Medicine and the Changing Order of the New York Academy of Medicine has created a subcommittee on industrial medicine consisting on April 26 of Drs. Anthony J. Lanza and Thomas D. Dublin. The purpose of the committee is to advance certain recommendations as to the developments that are indicated in the immediate future in the field of industrial health.

Physician Exonerated in Workmen's Compensation Inquiry.—Dr. Harry C. Stein, who was suspended for a year from rendering medical care under the workmen's compensation law as the result of the Moreland investigation in December 1943 on charges of having accepted "kickbacks," was exonerated by the appellate division and his suspension annulled newspapers reported The evidence in the hearing failed to show that the physician had received any such "kickbacks."

Meeting on Health Education.—The revision of "Suggested School Health Policies" was the object of a conference at Teachers College, Columbia University, April 19-21, under the auspices of the National Conference for Cooperation in Health Education. The document "Suggested School Health Policies" is an attempt to integrate the views of many professional groups regarding various phases of school health programs. Dr. Charles C. Wilson, professor of health education, Teachers College, was chairman of the meeting, and Justus J. Schifferes, New York, of the National Committee on School Health Policies, the secretary. The following representatives of the national organizations, comprising the National Committee on School Health Policies, were among those who attended the meeting:

Dr. William E. Ayling, Syracuse, N Y, American School Health Association.
Dr. Katherine Bain, Washington, D. C, Children's Bureau, U. S. Department of Labor.
Dr. William W. Bauer, Director, Bureau of Health Education, American Medical Association, Chicago
Edward S. Evenden, Ph.D, New York, American Teachers College Association.
W. H Lemmel, American Association of School Administrators, Washington, D. C.
S. S. Lifson, U. S. Public Health Service
Ben W. Miller, Ph.D., American Association for Health, Physical Education and Recreation, Washington.
Dr. Harold H. Mitchell, Long Island, N. Y, American Academy of Pediatrics.
Dorothy B. Nyswander, Ph.D., New York American Public Health Association.
Dr. Thurman B. Rice, Indianapolis, Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association.
Maycie K. Southall, Ph D., Nashville, Tenn Educational Policies Commission of the National Education Association
Frank Stafford, M A., U. S. Office of Education, Washington, D. C.
Alberta B. Wilson, R.N., National Organization for Public Health Nursing, New York.
J. M. Wisan, D D.S, Elizabeth, N J, American Dental Association.

Cornelius Rhoads Returns to Memorial Hospital.—Col. Cornelius P. Rhoads, M. C., since 1939 medical director of Memorial Hospital for the Treatment of Cancer and Allied Diseases, returned to his post April 15 after nearly two years' leave of absence, during which he was chief of the medical division of the Chemical Warfare Service of the Army of the United States. Dr. Rhoads is technically on leave until May 26, when he will be returned to "inactive status" subject to recall in case of emergency. On April 15 Major Gen. William N. Porter, chief of the Chemical Warfare Service, conferred on Dr. Rhoads the legion of merit for his work from June 1943 to April 1945, during which time he established the Toxicological Research Laboratory in the Edgewood Arsenal, Maryland, and the Medical Research Laboratory at Dugway Proving Ground, Tooele, Utah. He also established medical testing stations at Bushnell, Florida, and San Jose Island, Canal Zone. He developed new methods of diagnosis and treatment for the relief of injuries due to toxic chemicals, perfected a compound to counteract the effects of blister gas and all together perfected new technics and other contributions used beneficially during the war. Announcement was made also of a postwar development plan including the expansion of the hospital's present patient-care and laboratory research facilities and an extended clinical research and teaching program in cooperation with the city of New York through its contemplated hospital building for advanced cancer cases. This building will be erected on Memorial Hospital property adjacent to the present structure. The complete plant will provide 600 beds, the present capacity being 213.

OHIO

Prize for Essay on Premedical Education.—An award of $50 in war bonds was made to the Ohio Alpha Chapter of Alpha Epsilon Delta, national honorary premedical fraternity, at the Ohio State University, Columbus, for the prize winning essay "A Plan for Postwar Premedical Education," which the chapter submitted in an essay contest conducted by the fraternity's magazine, the *Scalpel*. On April 13 the award was presented by Maurice L. Moore, Ph.D., editor of the *Scalpel* and national secretary of Alpha Epsilon Delta, and director of the organic research division of Frederick Stearns & Company, Detroit, who lectured on "Sympathomimetic Agents."

Public Health Workshop.—A summer workshop in methods of visual communication will be given for the benefit of public health nurses by the Cleveland Health Museum. The workshop will be given for a three week period, June 18-July 6, at the Frances Payne Bolton School of Nursing, Western Reserve University, Cleveland. In announcing the course, Dr. Bruno Gebhard, the museum's director, stated that the workshop of the museum and its permanent and loan exhibits, study collections and health education reference material will be available to students. There will be a minimum of class instruction, and the students will work in small groups. The workshop is open to graduate registered nurses, especially those interested in public health, school and industrial nursing, and nurses in outpatient department and clinics, supervisors and teachers. Applications must be on file before June 1.

Advisory Tuberculosis Committee.—On April 12 Governor Frank J. Lausche named an advisory committee to assist in developing a state policy respecting tuberculosis. The members of the advisory committee comprise the membership of the advisory committee on coordination of tuberculosis programs of the Ohio Public Health Association. This committee has been at work on the problem for more than two years. The members of the governor's advisory committee are Drs. Roger E. Heering, Columbus, state director of health, chairman; Edgar C. Baker, Youngstown; Lynne E. Baker, Dayton; Willoughby D. Bishop, Greenville; Harold H. Brueckner, Lima; Charles A. Doan, Columbus; William D. Hickerson, Cincinnati; Clarence L. Hyde, Akron; Myron D. Miller, Columbus; Louis Mark, Columbus, Carl A. Wilzbach, Cincinnati; Joseph B. Stocklen, Cleveland, and John B. Hozier, Chicago. The lay members are W. K. Curfman Cincinnati; Charron Payne, Columbus, Delmar R. Serafy, Canton, and Floyd A. Rowe, Cleveland.

PENNSYLVANIA

Eighty Years of Age.—Dr. Tempest C. Miller, Abbottstown, said to be the oldest practicing physician in Adams County, observed his eightieth birthday March 22. He has practiced in Abbottstown for fifty-six years.

Society News.—Dr. Donald Guthrie, Sayre, will address the Harrisburg Academy of Medicine May 15 on "Diagnosis and Treatment of Tumors of the Breast."——At a meeting of the Lackawanna County Medical Society in Scranton, May 15, Dr. Charles Alexander Hatfield, Philadelphia, will discuss "Some Newer Diagnostic and Therapeutic Aids in the Treatment of Peripheral Vascular Disease." The society will be addressed May 22 by Dr. Bernard J. Alpers, Philadelphia, on "Effects of the War in Regard to Psychoneurosis and Other Mental Conditions." On May 29 Dr. William H. M. Erb, Chester, will discuss "Present Day Treatment of Varicose Veins."

Course in Psychosomatic Medicine.—A graduate course in psychosomatic medicine for the internist and general practioner will be conducted at Temple University School of Medicine and Hospital, June 3-30. The instructors will include Drs. Edward Weiss, professor of clinical medicine, Oliver

Spurgeon English, professor of psychiatry, and Gerald H. J. Pearson, associate professor of psychiatry. The course is designed to assist internists and practitioners of general medicine in the diagnosis and management of psychoneurotic and psychosomatic problems. It is not intended for specialization in psychiatry. The course will consist of lectures, seminars, conferences and clinical work in wards and the outpatient department. Additional information may be obtained from Dr. William N. Parkinson, Temple University Hospital, 3401 North Broad Street, Philadelphia 40.

Philadelphia

Personal.—Dr. Ralph Pemberton, professor of medicine in the Medico-Chirurgical College Graduate School of Medicine, University of Pennsylvania, has been elected president of the Pan American League for the Study and Control of Rheumatic Diseases, according to *Science.*

Special Lectures.—Edwin J. Cohn, Ph.D., professor of biochemistry and head of the department of physical chemistry, Harvard Medical School, Boston, delivered the fifth annual Phi Delta Epsilon Honor Lecture, April 27, at the University of Pennsylvania School of Medicine. His subject was "The Separation of Blood Derivatives, Their Natural Functions and Their Clinical Uses."——Dr. Alfred Blalock, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, gave the Phi Lambda Kappa Honor Lecture May 3 in the medical amphitheater in the Hospital of the University of Pennsylvania. His subject was "The Surgical Treatment of Certain Types of Disease of the Heart and Great Vessels."

TENNESSEE

Changes in Health Officers.—Dr. W. D. Burkhalter, Memphis, has resigned as assistant health officer of the Memphis and Shelby County Health Department, effective Dec. 31, 1944. Dr. Burkhalter, who will enter private practice, has been directing the child hygiene division and the crippled children service of the department since 1941.——Dr. John H. Morris, Pulaski, was recently elected health officer of Giles County to fill the unexpired term of the late Dr. James K. P. Blackburn.

Portrait of Walter Garrey.—On April 6 a portrait of Dr. Walter Eugene Garrey, professor emeritus of physiology, Vanderbilt University School of Medicine, Nashville, was presented to him by friends, students and associates. Dr. Frank H. Luton, professor of psychiatry at the medical school, presented the portrait, which was the work of Mrs. Frank Avent, local artist. The principal speaker was Howard J. Curtis, Ph.D., assistant professor of physiology, Columbia University College of Physicians and Surgeons, New York, who discussed "Excitation and Conduction in Nerve." Dr. Garrey had been a member of the faculty since 1925.

State Medical Election.—The Tennessee State Medical Association, during a business session of the house of delegates in Nashville, April 8, chose Dr. Charles M. Hamilton, Nashville, president-elect. Dr. William C. Chaney, Memphis, was installed as president to succeed Dr. Kyle C. Copenhaver, Knoxville. Dr. Harrison H. Shoulders, Nashville, secretary-editor of the association for the past seventeen years, resigned. The board of trustees of the association was empowered to name a temporary successor. Dr. Shoulders first declined the nomination, but in a spontaneous expression of appreciation for his service the delegates insisted on his election prior to acceptance of his resignation, according to the Nashville *Banner.*

WISCONSIN

Academy of Surgery.—On May 23 the Wisconsin Academy of Surgery will conduct a program at the St. Mary's Hospital, Racine, with the following speakers, all of Racine:

Dr. William R. Kreul, Curare as an Adjunct in Anesthesia.
Dr. Louis E. Fazen Jr., Surgical Management of Thrombophlebitis, with Case Report.
Dr. Edmund W. Schacht, Report on Gallbladder Surgery at St. Mary's Hospital.
Dr. Kenneth C. Kehl, Mechanism of Reflex Pain Originating in the Gall Duct System Causing Cardiac Pain.
Dr. Frederick C. Christensen, Plastics on the Breast—Presentation of Case.
Dr. Russell M. Kurten, Presentation of Cases of Skin Grafting in Trauma and Burns.

Dr. Geza de Takats, Chicago, will address the dinner session in the evening on "Thromboembolism."

Conference on Poliomyelitis.—May 24 has been tentatively selected as the date for a statewide conference of city health officers on poliomyelitis. The meeting will be in Milwaukee under the auspices of the state board of health and the local representatives of the National Foundation for Infantile Paralysis. Among the speakers will be Dr. John L. Lavan, Toledo, Ohio, director of research for the medical foundation. One of the objectives of the conference is to clarify thinking on the matter of area or regional age level quarantines, provisions for care of poliomyelitis cases, transportation facilities, follow-up of cases and related problems, the last to assist in a proposed uniform pattern of action by health officers throughout the state.

ALASKA

Basic Science Law Defeated.—*Northwest Medicine* announce the failure to pass a bill creating a basic science law, prepared by a professional bill writer and containing several mistakes that were not caught until after its introduction. The bill was passed by the senate but did not carry any appropriation for expenses of operating a board. It was tabled in the house until the last night of the session. During the second reading of the bill, an amendment providing membership on the board to consist of three nonmedical and two medical persons was passed. The senate asked the house to recede from this amendment, the house refused and the senate let the bill die, according to *Northwest Medicine.*

Mobile Health Boat.—A mobile health unit vessel, *Hygeno,* has been placed in operation for southeastern Alaska, supported by federal funds, to provide medical, nursing, x-ray, diagnostic, laboratory and sanitary services to many areas that have heretofore received little or no public health education. The vessel is equipped with x-ray and bacteriologic laboratories for diagnosis of tuberculosis, contagious diseases and control of epidemics. Dr. N. Berneta Block, director of the division of maternal and child health and crippled children's services, Juneau, has been temporarily appointed physician in charge. Mrs. Magnhild Oygard Bogue has been appointed nurse-technician, and at intervals a department sanitarian will join the staff for sanitary inspections in outlying areas.

GENERAL

National Noise Abatement Week.—April 29-May 5 was designated National Noise Abatement Week and devoted to the theme "Prescription for War Nerves—Stop Needless Noise—Keep Fit, Keep Well, Keep Working." The National Noise Abatement Council, 9 Rockefeller Plaza, New York, serves to promote the national consciousness for the elimination of needless noise.

Meeting of Medical Service Representatives.—Twenty-two representatives from Michigan, Indiana, Missouri, Iowa, Wisconsin and Illinois convened at the Palmer House April 22 with Dr. Charles H. Phifer, Chicago, chairman of the committee on the study of prepayment plans for medical and surgical care of the Illinois State Medical Society, presiding. Various problems were discussed.

Examinations in Ophthalmology.—The American Board of Ophthalmology will hold an examination in Los Angeles next January. It is expected that the examination dates will coincide with the dates of the midwinter course sponsored by the Research Study Club of Los Angeles, these dates to be announced later. Applications for this examination must be filed before September 1. For details prospective candidates should write at once to Dr. S. Judd Beach, secretary, Cape Cottage, Maine.

Narcotic Violations.—The U. S. Bureau of Narcotics announces the following actions:

Dr. Alpheus C. Koon, Lakeland, Fla., following his plea of guilty in the U. S. District Court at Tampa to the false execution of narcotic prescriptions, received on March 8 a prison sentence of two years and one day. The sentence was suspended and he was placed on probation for a period of five years.

Dr. Matthew Arnow, Jacksonville, Fla., pleaded nolo contendere in the U. S. District Court at Jacksonville to the false execution of narcotic prescriptions and received on March 26 a suspended prison sentence and was placed on probation for three years.

Joint Committee on Health Problems in Education.—The annual meeting of the joint committee on health problems in education of the National Education Association and the American Medical Association was held at the American Medical Association, May 8-9, to consider, among other subjects, the revision of "Suggested School Health Policies," school luncheons and health implications of a uniform military training program if adopted. Guests at the meeting included Dr. Roscoe L. Sensenich, South Bend, Ind.; Dr. Charles C. Wilson, professor of health and physical education, Teachers College, Columbia University, New York; Ruth Grout, Ph.D., associate professor of education, University of Minnesota, Minneapolis, and Col. Leonard G. Rowntree, M. C.

Tri-State Tuberculosis Group Formed.—The recent creation of the Association for the Rehabilitation of the Tuberculous is announced in the *Bulletin of the National Tuberculosis Association* for March. The new group includes the states of New York, New Jersey and Connecticut and aims to study the common problems and the development of work programs. Officers of the association are Marion C. Moore, rehabilitation secretary, Bergen County (N. J.) Tuberculosis and Health Association, president; Joseph Newman, educatioinal director, Municipal Sanatorium, Otisville, N. Y., vice president; Irma Minges, rehabilitation secretary, New York Tuberculosis and Health Association, secretary, and Walter Wenkert, rehabilitation service, National Tuberculosis Association, treasurer.

Physician Impersonated by Impostor.—Dr. René Bine, San Francisco, writes that a man has been traveling about the country using the name of his son, Dr. René Bine Jr., who is now serving overseas as a captain in the medical corps of the Army of the United States. One report describes the impostor as about 6 feet in height and weighing about 175 pounds; dark brown hair, gray blue eyes with a slight cast in the left eye. He appeared to be about 45 years old. The impostor seems to have a good background of medicine and carried a bag on which was printed "Dr. Rene Bines Jr., Grace Hospital, Detroit." Dr. Bine asks that persons be on the lookout for the impostor, pointing out that his son, who graduated at Stanford University School of Medicine, San Francisco, in 1941, is 29 years old and has been overseas thirty months.

Courses to Prepare Instructors in Sight-Saving.—The National Society for the Prevention of Blindness announces that five colleges and universities are cooperating with it in offering special courses for the preparation of supervisors, teachers, nurses and social workers and others concerned with the education of the partially seeing child. Elementary courses are being offered at Wayne University, Detroit, June 18-July 27; University of Wisconsin, Madison, June 25-August 17; and Teachers College, Columbia University, New York, July 2-August 10. Special short courses are being given at the University of Oregon, Eugene, June 18-July 27 and Indiana State Teachers College, Terre Haute, Ind., June 3-June 23. Additional information may be obtained from the National Society for the Prevention of Blindness, 1790 Broadway, New York.

Grants by Sugar Research Foundation.—Six grants amounting to $45,400, which were announced by the Sugar Research Foundation, April 16, include:

Pauline B. Mack, Ph.D., and associates of the Ellen H. Richards Institute, Pennsylvania State College, State College, Pa., $20,000 for one year, to measure the effect of high and low sugar containing diets on the health, growth and physical condition of children. In recommending this grant, Robert C. Hockett, Ph.D., scientific director of the foundation, pointed out that the institute has a collection of measurements and records from a mass nutritional study of 9,000 subjects which is probably not duplicated anywhere else.

Dr. Rachmiel Levine, director of metabolic and endocrine research, Michael Reese Hospital, Chicago, $7,500 for one year, to study the physiologic behavior of levulose, a sugar produced by inversion of ordinary sugar.

Dr. Israel L. Chaikoff, associate professor of physiology, University of California, Berkeley, $7,400 for two years, to study the protective action of sugar against cirrhosis of the liver.

Natural Resources Research Institute of the University of Wyoming, Laramie, $4,000 for one year, to investigate utilization of pectin from the pulp of sugar beets and to study derivatives of beet pectin.

Dora Stern, literature consultant, $4,000 for one year, to devise a system for classifying sugar derivatives and to compile a list of new derivatives discovered since 1930.

Dr. Israel M. Rabinowitch, McGill University Faculty of Medicine, Montreal, $2,500 for one year, to study further the body's relative rate of absorption of sucrose, dextrose and levulose

The foundation members include growers and processors of beet and cane sugar from the continental United States, Hawaii, Puerto Rico, Cuba, Canada and Haiti. Joseph F. Abbott, New York, is president.

Foundation for Tropical Medicine.—At the recent annual meeting of the American Foundation for Tropical Medicine Col. Thomas T. Mackie, M. C., was reelected president. Other officers include Dr. Henry E. Meleney, New York, vice president; Mrs. C. James Attarian, New York, acting secretary; Mr. William W. Lancaster, New York, treasurer, and Lee T. Melly, New York, executive director. During 1944 the foundation received $47,350 from twenty-five sources toward the work of the foundation, according to *Tropical Medicine News*. Eleven grants totaling $38,767 were made, of which seven were to medical schools in this country for the continuation of undergraduate teaching in tropical medicine, for research and for paying the expenses of technical assistance and supplies for teaching. The largest single contribution was made to the Tulane University of Louisiana School of Medicine, New Orleans, for budgetary needs of its department of tropical medicine. Another medical school was given financial assistance to provide a month's training for a technician at the Army Medical School in the latest technics of tropical medicine and parasitology. One of the most important contributions was to Duke University School of Medicine, Durham, N. C., for the establishment of a registry for mycotic diseases. A grant by the John and Mary R. Markle Foundation was made through the foundation to the Army Medical Museum for continuation of its preparation and distribution of teaching material in tropical medicine and medical parasitology.

CANADA

Chilean Physician Named to International Labor Office.—Dr. Marcos Charnes, Santiago, Chile, has been appointed scientific officer of the industrial hygiene service of the International Labour Office, Montreal, effective sometime in May. The position of director of this service had not yet been filled on April 28. The International organization still maintains a small staff in Geneva, Switzerland, and branch offices in Washington, London, Paris, New Delhi and Chungking.

PUERTO RICO

Proposed Medical Construction.—The Superior Educational Council of the University of Puerto Rico recently approved plans to establish a school of medicine and a school of nurses. The decision called for four "minimum guaranties" before the medical school could be projected: the construction and equipment of an adequate building for the school, the establishment of a modern 300 bed hospital in connection with the school, the selection and preparation of the faculty and technical personnel, and provision of necessary funds for operation of the school and hospital. An announcement indicated that the establishment of the school of medicine will have to wait until after the war but that the school of nurses would be constructed this summer. The four year course will consist of two years of academic studies and two years of clinical work, the latter to be conducted at the Bayamon district hospital. To offset the expenses of building and operating a medical school, it has been suggested that a scholarship fund be created to send fifty students each year to schools of medicine in the United States and Latin American countries (THE JOURNAL, May 27, 1944, p. 298, and Aug. 26, 1944, p. 1202). On April 26, in a special communication to the American Medical Association, it was stated that Governor Tugwell had vetoed a bill passed by the legislature to establish a school of medicine at the city of Ponce. The bill appropriated $400,000 for the proposed medical school but the governor, in a letter sent to Mayor Andres Grillasca of Ponce, stated that he would not approve the bill solely because he believed that it controverted the spirit of the University Statute of 1942, at which time a hard fight was made to make as certain as possible not only that the university should be exempt from partisan politics and patronage but that it should be lifted above controversies of any kind. The governor said that he would be naive if he "did not conclude from the nature of your campaign that you were trying to bring the school of medicine to Ponce for the sake of the city rather than for the good of the university." The city of San Juan was also campaigning to get the proposed school of medicine established at Rio Piedras, within the metropolitan area of the capital of the island. The governor in his letter to Mayor Grillasca stated that he could not "join an attempt to divide prosperity and prestige among competing communities." He added "I am not objecting to the establishment of the medical school at any site, including Ponce, I disapproved because I feel strongly that the university statute ought to be strengthened rather than weakened, and because this bill would lead definitely to its weakening." The controversy on the site for the proposed medical school arose when the Popular Democratic party, controlling the legislature, passed the bill with the understanding that the buildings for the school should be erected in Ponce. Puerto Rico, therefore, will not have this year the proposed school of medicine.

Deaths in Other Countries

Raymond C. Shannon, American entomologist and malarial expert, was found dead March 7 in his hotel in Port of Spain, Trinidad, aged 51.——**Sir Hubert Bond**, authority on mental diseases, died in Lancashire, England, aged 74.

The Promotion of Medical and Scientific Research in India

The physiologist A. V. Hill, secretary of the Royal Society, has visited India at the invitation of the government there to discuss and advise on Indian scientific research problems. The result is a valuable report by the only British scientist who has ever been asked to offer advice on a subject of tremendous importance for a subcontinent occupied by hundreds of millions of peoples, many with advanced oriental civilizations which are being rapidly modified by European culture. Professor Hill finds that there is great need for reforms. An Indian scientific office should be set up in London with specialists in various subjects, including medicine, representative Indian scientists should be attached to the British Commonwealth Scientific Office in Washington, and young Indian teachers and research workers should be given facilities for advanced study abroad, especially in Britain. The medical colleges should have full time teachers and research workers in all subjects. He recommends the establishment in Delhi of an all India medical center where selected students should be trained and receive financial aid in the form of scholarships. Such a center must be free from all racial, religious, political or provincial bias. Its purposes should be to provide the best type of teacher and research worker and thereby to foster throughout India a high standard of medical practice. He also recommends a special hospital for the clinical study of malaria and the bringing of existing research institutes into closer touch with the medical colleges.

To facilitate scientific research in general, Professor Hill wants to see a central organization under a minister without departmental duties. This organization should have six boards charged with research respectively in medicine, agriculture, industry, natural resources, engineering and defense. The director and principal administrative officer of each board should be ex officio a member of the other five, so as to maintain the closest liaison. There should be formed an Indian central register for scientific and technical personnel, and a central scientific academy, the equivalent of the Royal Society, he said. As scientific work in universities is the basis of progress in science, grants are necessary, and medicine and biology are the two subjects which badly need these. But Professor Hill feels the drawbacks of making research an entirely government subsidized affair, and the need for enlisting private benevolence in the endowment of scholarships and fellowships and other means whereby research is assisted.

The Improvement of Hospital Meals

Much dissatisfaction has been expressed with hospital meals, which are described as too monotonous and unappetizing. The subject has been taken up by the Ministry of Health, which has made recommendations to the hospital authorities. Official visits were paid to hospitals of various types by representatives of the Ministries of Health, of Labor and National Service and of Food. On their recommendations, suggestions for improved catering and feeding are based.

The minister of health, Mr. Willink, points out that the provision of hospital food necessitates a scientific approach, which involves questions of judicious purchasing, good cooking, palatability and the attractive presentation of the prepared food so as to ensure the nutritional requirements of all patients. An important recommendation is that a special committee might be appointed to deal with this side of hospital management, each of the various branches being represented. In larger hospitals it is recommended that catering be in charge of a full time officer suitably trained. In the smaller hospitals the work should be combined with the duties of another officer, or, alternatively, a full time officer should supervise and advise on catering in a group of hospitals. Other suggestions are made for planning and training courses. Fuller advantage might be taken of the advisory dietetic service of King Edward's Hospital Fund, as well as the expert staffs of the Ministry of Health in the regular visiting of hospitals.

Prevention of Malaria on Board Ship by Means of a Mosquito Repellant

A new measure for the prevention of malaria on board ships calling at malarious ports has been adopted. Ships going to tropical African ports and the East Indies must now carry a supply of dimethyl phthalate to be issued to the crew as a protection against mosquitoes when the vessel is in a malarious area. The instructions are that a few drops are to be applied to the exposed parts of the body, avoiding areas around the eyes and mouth, and to the clothing if the mosquitoes are biting through it. One application lasts four hours.

Anesthesia in War

According to a communication of Curtellet, consulting physician of the first French army, two modes of anesthesia are principally utilized in the primary evacuation hospitals, which receive the wounded directly from the combat line several hours after the wound has been received. These two methods are those of intravenous injections of pentothal and that of protoxide-ether in a closed circuit. These are delicate technics, but special centers for training in anesthesia have been so well organized that a total of 2,340 anesthesias of which 1,979 were done with pentothal did not result in a single miscalculation.

After numerous trials the mode of administration has been regulated in the following manner: The initial dose varies between 0.6 and 0.7 Gm. Then 0.1 Gm. is given successively when the patient becomes active. Under these conditions a perfect anesthesia of one or two hours will not require more than from 1.5 to 2 Gm. The only inconveniences of anesthesia with pentothal may consist in a laryngeal spasm due to the stimulation of the vagal irritability; sometimes, by reduction of the excitability of the bulbar respiratory centers, there may be a respiratory arrest lasting several seconds, which ceases after the immediate administration of oxygen under pressure. The grave syncopes are avoided by the system of fractionated doses. However, there are several contraindications; pentothal should not be employed in operations on the face, the neck and the mediastinum. It is not advisable for patients with severe anoxic shock or for those with abdominal wounds. On the other hand, it is satisfactory in those with cranial lesions and with wounds of the extremities. If this mode of anesthesia is used, it is indispensable to have on hand nikethamide as an antidote against the barbiturates, atropine against possible convulsive accidents and finally oxygen under pressure. Anesthesia with protoxide-ether-oxygen in closed circuit is preceded by a basal anesthesia, for instance by the intravenous administration of morphine. This anesthesia is advisable in all cases in which pentothal is contraindicated.

Colchicine and Cancer

Certain drugs, such as the alkaloids of the colchicine type, provoke abnormal mitoses and blockages of karyokinesis which end in the degeneration of cells rather than in their division. This property has made it possible to obtain in mice regression and even disappearance of tumors of the type of lymphoid

sarcoma. Similar results have been obtained on malignant and papillomatous tumors produced in rabbits by the virus of Shope.

However, in order to obtain these results toxic doses of colchicine are necessary. Nevertheless the usually tolerated doses, which produce only an elevation of the karyokinetic index without either blockage or degeneration of the cells, cause a sensitization of the cells to radiations. The cellular radiosensitivity is in fact related to the process of division.

Mallet reported at the Société of d'électrologie et de radiologie the results which he obtained on cancers of diverse localization by employing intravenous injections of colchicine from ten to twelve days before the application of roentgen therapy. Epitheliomas of the pharynx, larynx and tonsils seemed to regress more rapidly than with exclusive roentgen therapy. Cancers of the breast with cutaneous generalizations have been rapidly influenced: with a dose of 400 roentgens the nodules disappeared in about fifteen days. However, caution is necessary, because of the toxicity of colchicine, which causes agranulocytosis, diarrhea and febrile attacks.

These complications have induced Calvet, who discussed this question before the Société de chirurgie de Toulouse, to employ colchicine only in situ. Calvet stresses among other difficulties the difficulty of rendering a definite judgment about the cures possible by the combination of colchicine and radiations, because this therapy is relatively new. However, the results reported encourage the continuation of experiments with these karyokinetic poisons.

Chronic Rheumatoid Arthritis and the Nervous System

Charcot attributed the deformity of chronic rheumatoid arthritis to a reaction of the originally impaired nervous system, and more recently May and Laffite have identified a trophoneurotic type of rheumatic arthritis. A study of 16 cases of chronic rheumatoid arthritis led Martin to the following conclusions, which were presented before the Société médicale de Genève:

1. Certain disorders of the diencephalon, such as Parkinson's disease, assume the traits of a rheumatoid disorder before revealing their character as a disease of the nervous system.

2. A succession of purely nervous symptoms is frequently observed to dominate the clinical picture in certain cases of rheumatoid arthritis.

3. In a large number of cases of chronic rheumatoid arthritis neurologic signs are observed, such as modification of the reflexes, trophic disturbances, trembling, insomnia, cachexia, disturbances in the blood composition, disturbances of the regulation of the carbohydrates and even tetanic or fainting attacks.

The question arises whether the morbid element has its primary or secondary localization in the brain. At present the problem of the nervous origin of chronic rheumatoid arthritis remains unsolved.

Death of French Physicians

French medicine deplores the loss of a number of important scientists since 1940. Among them are Professors J. L. Faure, A. Gosset, Cuneo, Pierre Duval, Rathery, Sergent, Achard and Nobécourt, Dean Spillmann, de Nancy, d'Arsonval, Tréfouel, director of the Institute Pasteur of Paris, Claude Regaud, founder of the Radium Institute, Marchoux and Yersin both of the Institute Pasteur, Armand Carrel and Bandelac de Pariente.

Professor Roussy, member of the institute, who had been rector of the University of Paris at the onset of the war, has been recalled to that office. He has also been elected general secretary of the Académie de médecine.

BRAZIL

(From Our Regular Correspondent)

SÃO PAULO, April 3, 1945.

Medical Meetings

Two important medical congresses were held at São Paulo early in March. Many Brazilian doctors assembled to commemorate the fiftieth anniversary of the foundation of the Sociedade de Medicina e Cirurgia de São Paulo. The meeting was presided over by Prof. Carlos Gama of the department of neurology of the Faculdade de Medicina de Salvador, Baia. The official themes of the congress were "Arterial Hypotension" and "The Problem of the Hospital in São Paulo." The first was discussed by Prof. Aloysio de Castro, president of the National Academy of Medicine of Rio de Janeiro, and by Dr. J. Mesquita Sampaio, clinician in São Paulo. The question of hospital organization was discussed by Prof. Benedito Montenegro, director of the Faculdade de Medicina de São Paulo, and by Prof. Godoy Moreira, director of the Hospital das Clinicas of the same faculty. The problem of the rural hospitals was considered by Dr. Gama Rodrigues, a well known physician of Lorens. The congress devoted special sessions to the discussion of papers on trachoma, tuberculosis and rheumatism. Many other communications on other subjects were presented.

The other meeting was the first Congresso Medico-Social Brasileiro. The assembly was presided over by Prof. Antonio Candido de Camargo of the Faculdade de Medicina de São Paulo. Its program included the following items: (1) legal regulation of medical work in the hospitals; (2) legal regulation of medical work in private organizations; (3) the medical work in the industrial organization; (4) the medical work in the country zones; (5) insurance against diseases; (6) order of doctors; (7) providence institute; (8) assistance to parentless boys; (9) assistance to delinquent boys; (10) prenuptial medical examination; (11) medical assistance to country people; (12) standard medicine for poor people. All the topics were widely discussed. The conclusions of the congress were submitted to the governmental study.

Blood Groups Among Indians

There are many differences in the blood groupings of Brazilian Indians, when compared to the general population of North and South America. Although Drs. L. Ribeiro W. Berardinelli and M. Roiter had obtained only group O in 107 "guaranis" living in the south of Brazil, in 61 "carajás" of the north of that country Dr. Golden obtained 24 of group O, 3 of A, 31 of B and 3 of AB.

In 237 Indians from northeast Brazil Drs. E. Bioca and F. Ottensooser found only individuals belonging to group O. An examination of 50 Indians known to have or supposed to have some white blood, in the region of the Alto Rio Negro in the Estado do Amazonas, showed O 36, A 12, B 2 and AB O. These investigations confirm the data obtained by Blackfeet in the United States, Mazza in Argentina and Larreta in Peru, showing the preponderance of group O among Indians in America.

Marriages

WILLIAM REVERE WELLBORN Jr., Elkin, N. C., to Miss Lola Margaret Holcomb of Jonesville in Greenville, S. C., March 19.

JOHN WARREN REID, Mill City, Ore., to Miss Josephine Gresham Lockhart of Galveston, Texas, April 7.

ARTHUR B. SHAUL Jr., Cleveland, to Miss Mary Frances Hinds at Hudson, Ohio, March 8.

HARRY S. GRADLE to Miss Audrey Hayden, both of Chicago, April 28.

Deaths

Alfred Gibson Farmer ⊕ Dayton, Ohio; Kentucky University Medical Department, Louisville, 1904; from 1905 to 1915 engaged in medical service in the Panama Canal for the United States government, serving as physician at Gorgas Hospital at Panama, as district physician at Gatun, Corozal and Cristobal and as chief of the medical service in Colon Hospital; during World War I medical officer and post surgeon with rank of major, aviation service, U. S. Army, Wilbur Wright Aviation Field, and medical officer at the Army and Navy General Hospital in Hot Springs National Park, Ark.; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Otolaryngology and the Aero Medical Association; fellow of the American College of Surgeons; past president of the Montgomery County Medical Society; medical examiner for the Civil Aeronautics Authority; member of the staffs as ophthalmologist at the St. Elizabeth's and Good Samaritan hospitals; in 1935 chief of staff and since 1919 ophthalmologist of the Miami Valley Hospital, where he died April 2, aged 67, of cerebral hemorrhage.

Louis Fischer ⊕ New York; University of the City of New York Medical Department, 1884; secretary of the Section on Diseases of Children, 1899-1900, and Affiliate Fellow of the American Medical Association; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; formerly instructor in diseases in children at the New York Post-Graduate Medical School and Hospital; served on the staffs of the Sydenham, Willard Parker and Riverside hospitals in New York, and St. Vincent's Nursery and Babies Hospital in Montclair, N. J.; author of "Infant Feeding in Health and Disease," the "Health-Care of the Baby," "Diseases of Infancy and Childhood" and "Health-Care of the Growing Child"; died April 9, aged 80, of coronary thrombosis.

Albert Earle Boozer ⊕ Columbia, S. C.; University of Pennsylvania Department of Medicine, Philadelphia, 1892; since 1909 a member of the South Carolina State Board of Medical Examiners, serving as its secretary from 1911 to 1943 when he resigned; on the first board of physicians of Columbia Hospital; until a few years ago, when he resigned, served as medical director and examiner for the Carolina Life Company for about twenty years; assistant medical referee with the Mutual Life Insurance Company and medical referee of the Missouri Life Insurance Company, serving as examiner for twenty-five other insurance companies; died in Asheville, N. C.; March 1, aged 76, of generalized arteriosclerosis.

Sanders Lewis Christian ⊕ Medical Director, U. S. Public Health Service, retired, New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1912; fellow of the American College of Surgeons; served overseas during World War I and with the consular service in a medical capacity for many years, serving in London, Paris and Belgium; formerly assistant surgeon general and chief of the hospital division, U. S. Public Health Service; medical officer in charge of the U. S. Marine Hospital in San Francisco from 1940 to 1944, when he retired; died in the U. S. Marine Hospital March 9, aged 56, of acute peritonitis following perforation of a duodenal ulcer.

Claude William Asbury, Hymera, Ind.; Illinois Medical College, Chicago, 1903; formerly on the staff of the Union Hospital in Terre Haute; on the staff of the Mary Sherman Memorial Hospital, Sullivan; served during World War I; died in March, aged 67, of cerebral hemorrhage.

John K. Berk, Frackville, Pa.; Jefferson Medical College of Philadelphia, 1896; member of the American Medical Association; director of the First National Bank; member of the board of trustees of the Wernersville State Hospital in Wernersville; for many years surgeon for the Philadelphia and Reading Coal and Iron Company; company doctor for the Bell Telephone Company; member of the Rotary Club; died in the Pottsville Hospital, Pottsville, March 22, aged 73, of coronary thrombosis and renal insufficiency.

William Andrew Borders, Armuchee, Ga.; Atlanta Medical College, 1890; member of the American Medical Association; honorary member of the Medical Association of Georgia; on the staffs of the Harbin Hospital, McCall Hospital and the Floyd County Hospital in Rome, where he died January 15, aged 78, of cerebral hemorrhage.

Victor McMurry Brian ⊕ Lawrenceville, Ill.; George Washington University School of Medicine, Washington, D. C., 1917; served during World War I; on the staff of the Good Samaritan Hospital, Vincennes, Ind.; died in St. Louis March 27, aged 53, of cerebral hemorrhage.

Elmer Lee Burch, San Jose, Calif.; College of Physicians and Surgeons of San Francisco, 1905; died in the Alameda Hospital, Alameda, February 6, aged 75.

George M. Dill ⊕ Prescott, Wis.; University of Pennsylvania Department of Medicine, Philadelphia, 1895; died in St. Paul, January 30, aged 74, of uremia.

Henry Clay Eargle, Dublin, Texas; Fort Worth School of Medicine, Medical Department of Fort Worth University, 1905; died February 5, aged 62, of cardiac decompensation and arteriosclerosis.

Charles Henri Evans, Danville, Ill.; Illinois Medical College, Chicago, 1905; member of the American Medical Association and the Colorado State Medical Society; served with the British army during World War I; died in St. Elizabeth Hospital March 26, aged 69, of hypostatic pneumonia.

Abraham Judson Forman, Milwaukee; Marquette University School of Medicine, Milwaukee, 1936; member of the American Medical Association; interned at St. James Hospital in Butte, Mont.; began active duty as a captain in the medical corps, Army of the United States, on July 15, 1942; service terminated March 12, 1943; on the staffs of the Columbia, Mount Sinai and St. Mary's hospitals; died in a Port Washington hospital March 15, aged 40, of a skull fracture received in an automobile accident near Mequon.

Charles C. Gafford, Wymore, Neb.; College of Physicians and Surgeons, Keokuk, Iowa, 1881; member of the American Medical Association and honorary member of the Nebraska State Medical Association; died February 1, aged 86, of senility.

John T. Garland, Macon, Ga.; Vanderbilt University School of Medicine, Nashville, Tenn., 1878; died February 18, aged 88, of coronary occlusion.

Leigh Daniel Gillespie, Ardmore, Okla.; Baylor University College of Medicine, Dallas, Texas, 1904; member of the American Medical Association; died January 4, aged 75.

William W. Gregory ⊕ Stevens Point, Wis.; Rush Medical College, Chicago, 1897; member of the staff of St. Michael's Hospital; died in Madison January 30, aged 75, of cerebral hypertension.

George H. Grimmell Jr., Howard, Kan.; Barnes Medical College, St. Louis, 1896; member of the American Medical Association and honorary member of the Kansas Medical Society; died January 30, aged 89, of chronic myocarditis.

Fred William Hall ⊕ Chicago; Indiana University School of Medicine, Indianapolis, 1926; interned at the Methodist Hospital in Indianapolis; died March 14, aged 50.

Claud Cleburne Hardison, Lewisburg, Tenn.; University of Nashville Medical Department, 1890; Vanderbilt University School of Medicine, Nashville, 1890; died February 27, aged 75, of heart disease.

Frederick Smith Heller, Oakharbor, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1888; member of the American Medical Association, for many years physician for the Ottawa County Home; served on the staff of the Magruder Hospital, Port Clinton; in 1938 received a gold plaque from the Ottawa County Medical Society in honor of his fifty years of practice; died February 27, aged 81, of cerebral hemorrhage.

Carl Gottfried Johnson, Galesburg, Ill.; Long Island College Hospital, Brooklyn, 1892; member of the American Medical Association; in 1943 was made a member of the "Fifty Year Club" of the Illinois State Medical Society; served as a member of the city council and as commissioner of health; on the staff of the Galesburg Cottage Hospital; for many years a trustee of the Augustana College in Rock Island; died March 20, aged 80, of coronary thrombosis.

Harry Norton Kelley ⊕ Worcester, Mass.; Harvard Medical School, Boston, 1925; on the staff of St. Vincent's Hospital; died February 20, aged 45, of coronary thrombosis.

James Samuel King ⊕ St. Albans, Vt.; University of Vermont College of Medicine, Burlington, 1893; honorary member of the Vermont State Medical Society; served during World War I; died January 7, aged 74.

Charles Franklin Kivlin ⊕ Troy, N. Y.; Albany Medical College, 1898; served as district supervisor of the U. S. Public Health Service; on the staffs of St. Joseph's Maternity Hospital and the Troy Hospital, where he died March 21, aged 69, of coronary occlusion.

John Moser Kuhns, Freeburg, Pa.; Medico-Chirurgical College of Philadelphia, 1896; member of the American Medical Association; died in the Community Hospital, Sunbury, January 24, aged 73.

Lewis A. Ledford, Chattanooga, Tenn.; Southern College of Medicine and Surgery, Atlanta, 1914; at one time on the staff of the Chattanooga Hospital; died February 5, aged 68, of carcinoma.

William Duncan Mackechnie, Indianola, Neb.; Western University Faculty of Medicine, London, Ont., Canada, 1899; died in Boulder, Colo., March 4, aged 67, of cerebral hemorrhage.

John Henry Moore, Boston; Harvard Medical School, Boston, 1897; member of the American Medical Association; for many years medical examiner for the John Hancock Mutual Life Insurance Company; died in the Baker Memorial Hospital February 24, aged 75, of hypertensive heart disease and fracture of the right femur incurred in a fall.

Risdon Dent Moore, Springfield, Tenn.; Vanderbilt University School of Medicine, Nashville, 1890; member of the American Medical Association and honorary member of the Tennessee State Medical Association; served as city health officer; died in the Robertson County Hospital January 9, aged 87.

James Coleman Morehead, Flat Lick, Ky.; Louisville Medical College, 1902; died January 1, aged 69, of coronary thrombosis.

Samuel Murdock ⊕ Sabetha, Kan.; Kansas City (Mo.) Medical College, 1893; fellow of the American College of Surgeons; established the Sabetha Hospital, which he gave to the Sisters of the Order of St. Joseph and which is now known as St. Anthony Murdock Memorial Hospital, serving as its medical director; died February 26, aged 73, of myocardial failure.

Frank Blair Murphy ⊕ Akron, Ohio; Medical College of Virginia, Richmond, 1895; served on the staff of the People's Hospital, where he died March 30, aged 76, of cerebral hemorrhage.

Samuel Casper Murphy ⊕ Warsaw, Ind.; Indiana University School of Medicine, Indianapolis, 1910; served during World War I; medical superintendent of the Murphy Hospital; died February 10, aged 59, of lymphosarcoma

John A. Murray, Patton, Pa.; University of Maryland School of Medicine, Baltimore, 1885; Jefferson Medical College of Philadelphia, 1893; member of the American Medical Association; fellow of the American College of Surgeons; also a pharmacist; consulting surgeon and for many years surgical chief, Miners' Hospital of Northern Cambria, Spangler, which he assisted in establishing; a founder of the Clearfield Hospital in Clearfield; formerly U. S. Pension examiner; died February 27, aged 86, of chronic nephritis.

Robert Offenbach, Margate City, N. J.; University of the City of New York, 1879; died in the Atlantic City Hospital, Atlantic City, February 8, aged 85, of gastrointestinal hemorrhage from a ruptured duodenal diverticulum.

Robert Abner Partain, San Antonio, Texas; University of Texas School of Medicine, Galveston, 1927; member of the American Medical Association; served an internship at the Charity Hospital of Louisiana in New Orleans and a residency at the Central Louisiana State Hospital in Pineville, La.; on the staffs of the Robert B. Green Memorial Hospital and the Medical and Surgical Memorial Hospital, where he died February 15, aged 46, of coronary occlusion

Franklin James Pattenden ⊕ Asbury Park, N. J.; Long Island College of Medicine, Brooklyn, 1935; interned at the Fitkin Memorial Hospital in Neptune; died January 27, aged 34, of accidental carbon monoxide poisoning due to illuminating gas.

Edwin Francis Pierce, Lewiston, Maine; Columbia University College of Physicians and Surgeons, New York, 1901; member of the American Medical Association; surgeon on the consulting staff of the Central Maine General Hospital, where he died February 2, aged 72, of coronary thrombosis.

Frank McClung Postlethwaite ⊕ Kansas City, Mo.; University Medical College of Kansas City, 1913; on the staffs of St. Joseph's, Kansas City General, St. Mary's, St. Luke's and Trinity Lutheran hospitals; died March 22, aged 61, of coronary thrombosis.

Joseph Henry Potts, New Britain, Conn.; Dartmouth Medical School, Hanover, N. H., 1905; resigned in April 1934 as chairman of the board of park commissioners; director of the New Britain Memorial Hospital; on the staff of the New Britain General Hospital, where he died March 24, aged 65, of cerebral hemorrhage.

Charles-Jacob Price, Mount Morris, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1900; served in France during World War I; major, medical reserve corps, U. S. Army, not on active duty; died March 20, aged 70, of coronary occlusion.

Oscar Frank Reinhardt, Mascoutah, Ill.; Chicago College of Medicine and Surgery, 1908; member of the American Medical Association; served during World War I; died in St. Elizabeth Hospital, Belleville, March 11, aged 59, of bronchiectasis.

Carl Emery Richards, Sumner, Wash; University of Louisville Medical Department, Louisville, Ky., 1907; died February 13, aged 68.

Ernest Franklin Robinson ⊕ Kansas City, Mo.; University of Pennsylvania Department of Medicine, Philadelphia, 1896; an Affiliate Fellow of the American Medical Association; fellow of the American College of Surgeons; medical director of the Business Men's Assurance Company; on the staffs of the Research and St. Luke's hospitals; died February 5, aged 73, of coronary thrombosis.

Albert Walton Roth ⊕ Tulsa, Okla.; the Hahnemann Medical College and Hospital, Chicago, 1900; honorary member and in 1917 president of the Tulsa County Medical Society; founder and president of the Tulsa Public Health Association; member of the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; on the staff of the Hillcrest Memorial Hospital; died March 17, aged 71, of pulmonary edema and heart block.

Joseph Roth, Passaic, N. J.; New York Homeopathic Medical College and Hospital, New York, 1906; died in the Beth Israel Hospital March 20, aged 60, of postencephalitis.

Fritz Rubinstein, Woodhaven, N. Y.; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1923; served a residency at St. Joseph's Hospital for Consumptives in New York and the Rocky Glen Sanatorium in McConnelsville, Ohio; resident on the staff of St. Anthony's Hospital; died in New York December 6, aged 47.

Joseph Cheesman Thompson ⊕ Medical Inspector, Commander, U. S. Navy, retired, San Francisco; Columbia University College of Physicians and Surgeons, New York, 1896; entered the U. S. Navy on Nov. 26, 1897; retired Nov. 15, 1929 on his own application after thirty years' service; died March 7, 1943, aged 68, of heart disease.

Stephen Tarnoczi Turney ⊕ Barberton, Ohio; Ohio State University College of Medicine, Columbus, 1931; interned at the Charity Hospital in New Orleans; on the staff of the Citizens Hospital; died in the Cleveland Clinic Hospital, Cleveland, February 13, aged 43, of respiratory failure following laminectomy.

Francis Raymond Ward, New York; University of the City of New York Medical Department, New York, 1890; died December 18, aged 77.

Henry C. Werner ⊕ Fond du Lac, Wis.; Wisconsin College of Physicians and Surgeons, Milwaukee, 1905; member of the American Psychiatric Association; superintendent of the Wisconsin Memorial Hospital in Mendota from 1927 to 1933 and the Southern Wisconsin Colony and Training School in Union Grove from 1917 to 1923; died February 6, aged 70, of carcinoma of the prostate.

William Francis Willoughby, Englewood, N. J.; New York Homeopathic Medical College and Flower Hospital, New York, 1913; assistant medical examiner for Bergen County; served as a member of the Englewood Board of Health for many years; a member of the medical staff of the Englewood Hospital; died February 28, aged 60, of cerebral hemorrhage and hypertension.

Charles M. Wood ⊕ Maroa, Ill.; Northwestern University Medical School, Chicago, 1894; served on the staffs of the Decatur and Macon County Hospital and St. Mary's Hospital in Decatur; died in the West Suburban Hospital, Oak Park, February 25, aged 73, of diabetes mellitus.

PUBLIC HEALTH SERVICE

Orestus D. Adamson, Sabine, Texas; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1912; acting assistant surgeon in the U. S. Public Health Service; medical officer in charge of U. S. Quarantine Station at the time of his death; died in the U. S. Marine Hospital, Galveston, February 13, aged 66, of heart disease.

Correspondence

BLOOD AND SPINAL FLUID TESTS FOR SYPHILIS IN MALARIAL PATIENTS

To the Editor:—The article "Blood and Spinal Fluid Tests for Syphilis in Malarial Patients," by Harold W. Potter, Lewin H. Bronstein and Charles M. Grüber (THE JOURNAL, March 24, p. 699) is excellent evidence for the occurrence of nonspecific syphilis reactions in "natural" malaria. To make these observations completely useful, it is necessary to look at them from the opposite side too and establish the conditions under which a positive serologic reaction may be accepted with no more criticism than is always required in evaluating serotests for syphilis. The authors have not overlooked this, but more emphasis is advisable if we don't want to err by leaning back too far.

The clearcut experiences on inoculated malaria, although not applicable without discernment, should facilitate orientation in the more intricate maze of natural malaria. The regular occurrence of positive syphilis reactions in nonsyphilitic persons inoculated with malaria was first described by Ludwig Horn (*Jahrb. f. Psychiat. u. Neurol.* **43**:247, 1924). His results were confirmed by subsequent investigators. The facts (also derived from unpublished observations) were that every case becomes distinctly seropositive after the sixth fever bout; every case becomes seronegative again within eight weeks after termination of malaria; the most sensitive test (at that time the Wassermann reaction with R. Mueller's antigen) becomes positive sooner and stays so longer than the less sensitive ones (at that time Meinicke's earlier methods and the Sachs-Georgi reaction).

Although these observations were made only on inoculation with a strain of Plasmodium vivax acclimatized to transmission from man to man, there is no reason to assume a smaller percentage of positive reactions during a limited period of natural malaria. As for the return to negativity, such a straight conclusion is not permitted, because of circumstances that are too complicated to be discussed here. An indirect approach can be gained by performing the Henry test (*Arch. Inst. prophylac.* **1**:341, 1929) in inoculation malaria (Brandt, Robert, and Horn, Ludwig: *Klin. Wchnschr.* **14**:1538 [Oct. 26] 1935). The curve of reactions, from negative to positive to negative, closely resembles the curve of the nonspecific reactions for syphilis. As Henry describes the behavior of his test in malaria disease just the way we found it in malaria inoculation, we may expect the same parallelism also in the nonspecific syphilis reactions, meaning that, a certain time after cessation of fever attacks, malaria does not produce such reactions (except, of course, in an indirect manner e. g. by having caused liver damage that outlasts the actual infection). A negative Henry test, therefore, by indicating that the period of manifest malaria infection has passed, would enhance the dependability of a positive syphilis reaction, where malaria has to be taken into account.

We can also supply a direct contribution. After the last war the number of patients with a history of malaria was considerable among former Austrian soldiers. Since at that time the introduction of routine serologic examination on the one hand and the progressively increased sensitivity of the tests (in our case the Mueller conglobation reaction) on the other hand furnished a great number of unexpected positive reactions, the question of specificity was foremost in our minds. We explored every such case for nonspecificity, applying all the required criteria. These extensive investigations did not present the slightest indication that, beyond the stage of attacks, malaria has any influence on the outcome of serologic syphilis reaction.

Altogether, the average percentage of positive reactions in nonsyphilitic persons does not give the full picture. During the manifest disease we must expect a much higher incidence, but afterward the percentage soon reaches zero.

ROBERT BRANDT, M.D., Cincinnati.

USE OF MAGNET FOR REMOVAL OF FOREIGN BODIES

To the Editor:—In the January 13 issue of THE JOURNAL, under Clinical Notes, Dr. Murdock Equen reports "A New Magnet for Foreign Bodies in the Food and Air Passages." The widespread newspaper, trade journal and magazine coverage of the original use by us of the Alnico magnet for this purpose in June 1943 was perhaps considered too well known to require quoting as the source of the method employed by Dr. Equen.

However, there are medical references of which Dr. Equen was apparently unaware when he requested a duplicate of the magnet we employed from General Electric. Our case was reported at a meeting of the Section on Otology, Rhinology and Laryngology of the Medical Society of the County of Kings and Academy of Medicine of Brooklyn, Nov. 10, 1943. Dr. Moorehead and Dr. Clerf, who discussed our paper, predicted the future usefulness and easy general applicability of the method, which our continued use and Dr. Equen's communication some fifteen months later confirms.

The original article presenting the use of the Alnico magnet was published in the *Annals of Otology, Rhinology & Laryngology* (**53**:589 [Sept.] 1944) and was entitled "The Use of a Permanent (Alnico) Magnet in the Peroral Removal of a Metallic Foreign Body (Padlock) from the Stomach," by Samuel Silber, M.D., Carl Kaplan, M.D., and Bernard Epstein, M.D.

It should be further noted that the magnet was not new even when we used it. The only thing new about it was the search by one of us (S. S.) for such an instrument to serve the specific purpose of removing a swallowed magnetic foreign body. This search led to an industrial plant, which like many others, began using the Alnico magnet in a wide variety of machines soon after it was first introduced by the General Electric Company in 1935.

We believe that the interests of historical accuracy and your high standards will be served by this addendum.

SAMUEL SILBER, M.D.
CARL KAPLAN, M.D.
BERNARD S. EPSTEIN, M.D.
Brooklyn.

MEDICAL COLLEGE OF SOUTH CAROLINA

To the Editor:—In THE JOURNAL for March 31, page 867, there is a statement relative to affairs in South Carolina which misrepresents the situation rather seriously and I beg you to publish this correction.

The commissioners of the Roper Hospital have not opposed the expansion program of the medical college except as far as the building of a large hospital is concerned, feeling that the addition to the Roper Hospital now under construction would furnish the facilities needed for larger classes. The commissioners were authorized by the medical society to give full publicity to their proposal and they thought they were carrying out the expressed wishes of the society in acting as they did. The society had at no time approved the program in toto but only in principle, and the commissioners expressed definitely their approval of expanding the teaching facilities of the college and their willingness to cooperate.

A few days after passing the condemnatory resolution, the society passed another resolution expressing confidence in the board of commissioners. I am asking you to publish this letter in justice to the commissioners, whose attitude and whose actions have been misrepresented.

ROBERT WILSON, M.D., Charleston, S. C.
Dean Emeritus, Medical College of the State of South Carolina.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Venereal Disease: Breaking of Quarantine as a Punishable Offense.—The relator, because of being infected with venereal disease, was committed to "communicable disease isolation quarters." She escaped from those quarters, was subsequently apprehended and fined $25 for breaking quarantine and was committed to jail until payment of the fine. She filed a petition for habeas corpus on the ground that no law in Tennessee, the state in which she was committed, provides for fine and imprisonment as a penalty for leaving or escaping from quarantine. The trial judge ordered her discharge from jail but remanded her to the communicable disease isolation quarters from which she had escaped. The sheriff, the custodian of the jail, appealed to the Supreme Court of Tennessee.

The sole question to be determined here, said the supreme court, is whether or not the statutes of Tennessee provide for punishment by fine of one who leaves quarantine without permission of the health officer in charge. Chapter I of title 13, Code of Tennessee, 1932, deals comprehensively with the general subject of "Preventing the Spread of Disease," and article VII specifically deals with syphilis and other venereal diseases, which are defined in the code, section 5813, as amended, and declared to be "communicable, and dangerous to the public health." By section 5816, as amended, health officers are empowered to "make examinations of persons reasonably suspected . . ." of "being infected with a venereal disease of a communicable nature" and, "when in the judgment of the state, municipal or county health officer, it is necessary to protect the public health, to isolate and quarantine persons infected with a venereal disease." The relator having been found to be so infected and thereon placed in quarantine, it cannot be questioned, in view of the code provisions just referred to, that her isolation and quarantine confinement by the health officers was lawful. It is the general rule, continued the court, that one who breaks a lawful quarantine is subject to punishment for so doing. See 12 R. C. L. 1292 and cases cited in notes. Furthermore, the code, section 5818, as amended, provides that "No one but a state, municipal, district or county health officer or his duly authorized representative shall establish and terminate isolation or quarantine of persons infected with venereal diseases." Also that "the release of a person from isolation or quarantine shall be made when in the judgment of the health officer the disease is no longer communicable."

The sheriff relied on the provisions cited for enforced segregation and quarantine of those found to be afflicted with such contagious diseases and for the termination of such isolation or quarantine only by a health officer and as justifying the imposition of the fine on the relator, invoked section 5824, *ibid*, which provides that:

> Any health officer or *any other person* who fails to perform the duties required of him in this statute, or violates any of the provisions of same, or of any rule or by-law promulgated under its authority, shall be guilty of a misdemeanor, and be fined not less than twenty-five dollars and not more than five hundred dollars, and each violation shall be a separate offense.

No stretch of construction, said the Supreme Court, is required to bring relator within the descriptive phrase "any other person," as italicized. It seems reasonably clear that one who has been placed in quarantine "fails to perform the duties required of him" and violates a basic purpose of the statute, when he leaves quarantine against the orders of those in charge and thereby subjects himself to the penalty provided by this code section. The whole scheme of segregation and isolation by quarantine would be ineffectual and frustrated unless an obligation is imposed on those found necessary to place in quarantine to observe its isolation restrictions. Moreover, supporting this view, by code, section 5822, it is provided that "The state department of health is empowered and directed to make such rules and by-laws for the . . . isolating and quarantining of infected persons as it may, from time to time, deem advisable." A copy of "regulations" issued by the department is brought up with the record on the appeal and "regulation 13" therein provides that:

> (A) Every person who is infected with a communicable disease, who is a carrier of the infection of a communicable disease, who is suspected of having a communicable disease or who is a contact with a case of communicable disease shall strictly observe and comply with all orders, isolation and quarantine regulations and restrictions given or imposed by the local health officer or the State Department of Public Health, in conformity with law and pursuant to these regulations

One who fails and refuses to "observe and comply with" such isolation and quarantine regulations violates a duty imposed on him by law and is not only subject to the penalty provided by the foregoing section 5824 but is guilty under code section 11054, declaring it a misdemeanor for one confined in a workhouse or jail on any charge of a criminal offense *"or otherwise lawfully so confined"* to escape or attempt to escape therefrom. The language italicized would seem to include one lawfully confined in quarantine. And, finally, under article V of this same chapter, subhead "Prevention of Communicable Diseases," appears code section 5793, which expressly provides for fine and imprisonment of "any person isolated or quarantined who shall wilfully escape . . . before he has fully recovered," and so on, which would seem to have application. It is true that venereal diseases were excepted from communicable diseases dealt with under this article, code section 5789, but, as has been seen, by subsequent enactment (code section 5813) venereal diseases are expressly declared to be communicable diseases subject to quarantine, so that, in application of the pari materia rule, this provision for punishment may well be extended to those quarantined for such diseases who escape before recovery. But, however this may be, on the grounds hereinbefore set forth, we hold that the relator was lawfully in isolation and confinement and was subject to fine for having escaped therefrom. Her detention was therefore not illegal and the judgment below must be reversed. Accordingly, apparently, the prisoner was remanded to the custody of the sheriff. —*State ex rel. Kennedy v. Head, Sheriff, 185 S. W. (2d) 530 (Tenn., 1945).*

NATIONAL BOARD OF MEDICAL EXAMINERS. Parts I and II, July 16-18. Part III. Various centers, June. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th St., Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF INTERNAL MEDICINE: *Oral.* New Orleans, May 21-23, Philadelphia, June 6-8 and Chicago, June 27-29. San Francisco, Oct. 15-17. *Written.* Various centers, Oct. 15. Final date for filing application is Aug. 1. Candidates in the armed forces may take the examination at their station with the permission of their medical commanding officer. Asst. Sec., Dr. W. A. Werrell, 1301 University Ave., Madison 5, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY. Chicago, May 28. Sec., Dr. Paul Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OBSTETRICS & GYNECOLOGY. *Part II. Oral.* Atlantic City, June 13-19. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY. New York, June 13-16, Chicago, Oct. 4-6; and Los Angeles, January. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY. *Part I. Oral and Written.* New Orleans, Sept. 28-29, Philadelphia, Oct. 5-6, Chicago, Oct. 12-13 and San Francisco, Oct. 19-20. Final date for filing application is August 1. Sec., Dr. G. A. Caldwell, 3503 Prytania St., New Orleans 15.

AMERICAN BOARD OF OTOLARYNGOLOGY. Chicago, Oct. 3-6. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PATHOLOGY. Philadelphia, June 13-14. Final date for filing application is May 15. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit 2.

AMERICAN BOARD OF SURGERY. *Written.* Various centers, October. Final date for filing application is Aug. 1. Sec., J. S. Rodman, 225 S. 15th St., Philadelphia 2.

AMERICAN BOARD OF UROLOGY. *Written.* Chicago, Dec. 9. *Oral.* Chicago, Feb. 19-22. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Physiology, Baltimore

Dislocations of Shoulder. L. F. Bush.—p. 520.
*Local Treatment of Burns with Pressure Dressings and Films Containing Sulfonamide. E. C. Reese.—p. 524.

Pressure Dressings and Films Containing Sulfonamides in Burns.—Reese reports results obtained in 43 cases of burns treated with films containing sulfonamides held in place by pressure dressings. The film used was 0.004 inch thick, transparent and pliable, and it conformed easily to body surfaces. The base of the film was methylcellulose, to which was added triethanolamine in addition to a plasticizer. The standard film employed contained 20 per cent sulfanilamide and 10 per cent sulfacetimide. It was estimated that 1 sq. cm. of the film contains 3 mg. of the sulfonamide. Recently 0.5 per cent proflavine has been added to the film. Triethanolamine was used in this film because it maintains the hydrogen ion concentration of the surrounding medium at a slightly alkaline reaction (p_H 8.5), which enhances the effectiveness of sulfanilamide. Utmost aseptic precautions were taken. In 39 cases the burns were second degree, in 4 cases second and third degree burns were present. Reese found that the healing time with this treatment compares favorably with most of the accepted methods of therapy. The film appears to possess an important advantage in that it forms a protective transparent coating which is not removed until full healing has occurred. Painful redressings are thus eliminated, and injury to partially devitalized structures and fragile newly growing epithelium is prevented.

Frozen Plasma.—Fresh blood plasma, prepared according to the directions of the Central Institute for Blood Transfusions in ampules or bottles, is placed in a freezing chamber at temperatures of from −15 to −25 C. Before transfusion plasma is thawed by placing the unopened containers into a water bath at a constant temperature of 38 to 40 C. The time required for thawing and warming averages twenty minutes. Only in rare cases does residual flocculation necessitate filtration of plasma. Determinations of viscosity, turbidity, protein fraction and refractive index were carried out before freezing and after thawing. These investigations established the absence of irreversible physicochemical changes of the proteins. The use of

frozen plasma does not cause toxic effects The therapeutic effect of transfused thawed blood plasma is the same as with fresh plasma. Thawed plasma may be used for the same diseases and in the same doses as fresh blood. Like fresh plasma, it is the best blood substitute.

Stimulation of Wound Healing by Embryonal Tissue.—Goldberg prepared embryonal extracts in a castor oil emulsion or petrolatum ointment. Since war wounds are contaminated, 0 3 or 0 5 per cent of xeroform or 0 5 to 1 per cent of sulfanilamide was added. Ointments with a petrolatum base containing embryonal tissue were used in the clinics and hospitals of the Siberian military medical units beginning with July 1942. Petrolatum ointments are more convenient in the treatment of superficial wounds and of ulcers, since they remain in contact longer with the wound surface. The emulsion in castor oil produced sensations of burning and irritation of the surrounding skin. The same emulsion in petrolatum facilitated the filling of osseous defects after sequestrotomy The 15 per cent ointment proved more effective than the 5 per cent emulsion previously used and replaced the emulsion in evacuation hospitals and clinics in wounds of soft tissues with or without periostitis and fracture, *in sluggish wounds in denervated tissue*, in chronic wounds in stumps with or without osteomyelitis, in sluggish ulcers from varicosities, burns and frostbite, and for filling osseous defects after sequestrotomy Embryonal emulsion in ointment form stimulated the growth of epithelium and fibroblasts. Wound exudates diminished after treatment with 15 and 25 per cent ointments. Granulation tissue appeared earlier and grew more intensively than in control cases. Epithelization was rapid, with penetration of epithelial strands into the granulation tissue. Cornification of epithelium was hastened.

Isoimmunity to Rh Factor and Transfusion Reactions.—In order to obtain some perspective on the incidence of isoimmunity to the Rh factor in a general transfusion service De Gowin studied 5,386 consecutive blood transfusions at the University of Iowa Hospitals Multiple transfusions were given to recipients without regard to Rh type or to obstetric history of female recipents. Transfusion reactions of all types were studied for evidence of isoimmunization with the Rh factor. In 3,132 transfusions given to 1,112 males, the incidence of reactions was 3.1 ± 0.2 per cent. In 1,004 female recipients of all ages the incidence of reactions was 3.9 ± 0.4 per cent in 2,254 transfusions. This is considered to be a statistically significant difference in the sexes which may possibly be explained by isoimmunity to the Rh factor developed during pregnancy. In the 186 transfusion reactions of all types, only 6 could be attributed to isoimmunity to the Rh factor. Isoimmunity was attributed to multiple transfusions in 4 instances and to pregnancy in 2. There was a fatality from transfusion of Rh positive blood into a recipient who had been sensitized by multiple transfusions. It is estimated that of the 399 recipients receiving four or more transfusions approximately 60 were Rh negative. Only 4 of these were immunized to the Rh factor by multiple blood transfusions The case histories of the 6 recipients with isoimmune reactions are reported Preliminary cross matching for the anti-Rh agglutinin would not have prevented all of the reactions. The author shows that there are many difficulties in testing for Rh incompatibilities, such as lack of sources of Rh typing serums and of adequate methods of demonstrating anti-Rh antibodies in the laboratory. It is frequently necessary to work with weak anti-Rh agglutinins in cross matching blood. The time required for incubation of cell-serum suspensions for the

demonstration of the anti-Rh agglutinin (from thirty to sixty minutes) imposes a serious delay if the transfusion is an emergency treatment, and, since the delay is considered more dangerous than the possibility of a reaction from Rh incompatible blood, the Blood Transfusion Service has decided to forego the incubation of cell suspensions preliminary to urgent transfusions.

Posterior Herniation of Lumbar Intervertebral Disks.—Munro believes that a clinical diagnosis of a posterior herniation of the nucleus pulposus of a ruptured lumbar intervertebral disk which is based only on the history and physical and neurologic examinations, if unconfirmed by other objective findings, is at best only a "possible" diagnosis. Surgery is not justified under such circumstances. If one can demonstrate a sensory deficit that corresponds to the peripheral distribution of a low lumbar or upper sacral root, together with atrophy and loss of ankle jerk in the same leg, a diagnosis of irritation or compression of this particular root is justified. If in addition there is a history of intermittent attacks of pain in the back with radiation to any part of the leg, especially to the lower part of the leg, which is associated with initiation or increase of the typical pain by coughing, sneezing or straining or by back motion or lifting, and if these attacks started after a back injury, back strain, lifting strain or fall, a posterior herniation of either the fourth lumbar or lumbosacral disk must be seriously considered as a cause of the radiculitis. This cannot be regarded as a certainty, however, unless confirmed by other and more accurate data. A positive straight leg raising or Lasègue test, limitation or loss of back motion, a change in the lumbar curve, spasm of the erector spinae muscles and local tenderness in the lumbosacral area indicate only that the patient has some trouble with the lower part of his back, lumbosacral roots or cauda equina and neither confirm nor deny the diagnosis of a herniation. A history and examination such as given, if accompanied by a partial or complete dynamic block or an increase in the total protein of a sample of cerebrospinal fluid properly collected from below the level of the block, or both of these, justify a diagnosis of irritation or compression of any part or all the cauda equina and a probable diagnosis of either an intraspinal tumor or a midline posterior herniation of a lumbar disk. Final differentiation must at least await myelography and in many cases operation. The level of herniation is usually not determinable on the basis of pure clinical data. Multiple herniations cannot be diagnosed without adequate preoperative visualization of the lower subarachnoid space. Certain diagnosis, both concerning the presence of a herniation or herniations and concerning the level, depends on adequate visualization of the lumbosacral subarachnoid space by some opaque contrast medium. Skiodan in 20 per cent solution has proved satisfactory for this purpose.

Local Application of Sulfathiazole in Incisions.—Seventy incisions for lobectomies and pneumonectomies were studied. The incisions passed through the skin and subcutaneous tissue, posteriorly through the trapezius and rhomboid muscles and anteriorly through the latissimus dorsi and serratus anterior. The control or prior groups consisted of 35 patients. The experimental group consisted of the 35 patients operated on in the period immediately following that in which the control group of patients came to operation. In this experimental group not more than 2 Gm. of sterilized sulfathiazole powder was rubbed into every nook and cranny of the extensive incisions before opening into the pleural cavity, thus producing a film of serum and blood saturated with sulfathiazole overlying all of the exposed tissue. Thirteen wound infections occurred in the control group, while only 4 occurred in the experimental group. Sulfathiazole applied locally in the experimental series was the only important factor to which the reduced incidence of wound infection in the experimental group could be attributed.

Casual and Basal Blood Pressures.—Smirk defines casual blood pressure as the sum of the basal blood pressure and the supplemental pressure; this last represents the degree of blood pressure elevation above the basal level due to whatever degree of physical, emotional and suprabasal metabolic activity is present at the time of blood pressure measurement. The basal pressure is the pressure measured at a time when physical, emotional and metabolic activity are reduced to a physiologic minimum. Failure to obtain the true basal reading will not always be apparent to the observer, especially when the failure is due to emotional reasons. Both normal and hypertensive subjects with a high basal pressure have a greater statistical expectation of having a high casual pressure than do those whose basal pressure is low. Likewise those with high supplemental pressures have a greater statistical expectation of a high casual pressure than do those whose supplemental pressure is low. In comparing one individual with another the basal and supplemental pressures, on the other hand, are independent variables in the sense that the level of the basal blood pressure in an individual is no guide to the probable level of the supplemental pressure. Most statistics concerning the level of the blood pressure are concerned with the casual readings. The fact that, when comparing 1 individual with another, within a comparable physiologic group, the casual blood pressure is to be regarded as the sum of two independent variables has statistical implications. The supplemental pressure forms a significantly higher proportion of the casual pressure among patients with essential hypertension than among normal subjects. An improved method is recommended for determining the basal blood pressure.

Magnesium Sulfate to Prevent Toxic Effects of Mercurial Diuretics.—Pines and his associates state that an analysis of toxic symptoms and signs which appear after mercurial diuretics proves that some of them depend on the drug itself and not on the diuresis. The mercuric ion liberated from organic mercurials produces abundant diuresis through its action on the renal tubules, but simultaneously in certain doses, and if appearing rapidly in the blood stream of a mammal, it provokes serious disturbances in the conduction system of the heart as well as in the musculature of the ventricles. The authors studied the course of acute intoxication produced by the intravenous or intracardiac injections of esidrone on normal dogs with the help of the electrocardiograph. They concluded from these studies that mercurial diuretics in certain doses are general depressants for the whole cardiac muscle. The following pattern of intoxication was observed: changes of T waves, intraventricular and auriculoventricular conduction disturbances, diminution of frequency of impulse formation in the sinoauricular node, ventricular paroxysmal tachycardia, chaotic heart action, ventricular fibrillation and death. The addition of small quantities of magnesium sulfate (0.5 cc. of a 20 per cent solution) prevents ventricular fibrillation and death even if doses seven times higher than normal lethal doses are used. Magnesium sulfate does not prevent and perhaps even increases the conduction disturbances resulting from the administration of lethal doses of mercurial diuretics. On the other hand, such amounts of magnesium sulfate increase the diuretic response, are entirely safe and mix with mercurial diuretics without forming any precipitate. It is suggested that small quantities of magnesium sulfate be incorporated into the mercurial diuretics in order to prevent fatal reactions sometimes resulting from the intravenous injections of these drugs.

Elimination of Cross Infection: An Experiment. H. P. Pickerill and Cecily M. Pickerill.—p. 159.

Chemotherapy of Sonne Dysentery.—Swyer and Yang say that of 179 patients with bacteriologically proved Sonne dysentery 41 were treated with sulfanilylbenzamide, 112 with sulfanilylamidobenzamide and 26 with succinylsulfathiazole. The stools became formed, normal in color and free from blood or mucus in twenty-four to forty-eight hours in the sulfanilylbenzamide series, and in 38 of these cases bacteriologic clearance was obtained in an average of 1.8 days. Improvement in characteristics of stools was well defined with sulfanilylamidobenzamide but rather less so than with sulfanilylbenzamide. The average time for clearance was 3.6 and 2.5 days with full and half dosage respectively. With succinylsulfathiazole there was not a great improvement in stools, but clearance time was 2.4 days. Bacteriologic relapse rates were 7.3 per cent with sulfanilylbenzamide, 15 per cent with a full dose of sulfanilylamidobenzamide and 3.3 per cent with a half dose and 34.6 per cent with succinylsulfathiazole.

Deliberate Liver Puncture.—Deliberate liver puncture is the term coined by Kalk and his associates to designate a method in which the macroscopic examination of the liver by laparoscopy was combined with liver puncture for the purpose of microscopic examination. Puncture was performed under local anesthesia by means of a cannula of Roholm and Iversen's type after the introduction of the laparoscope into the air filled abdomen. This cannula is 2 mm. thick and has four fine teeth at its end, which may produce a sawlike effect on rotation. The cannula is graduated at a distance of from 3 or 4 cm. from its end so that it may not be inserted too far into the liver. In cases of diffuse changes of the liver, i. e. in parenchymatous icterus or in icterus due to obstruction, the puncture was carried out at a distance of from 5 to 7 cm. from the anterior border of the liver. The danger of hemorrhage may be prevented by this method, which has been used 123 times within two years. One additional advantage for this method is the fact that puncture of the left lobe of the liver may be carried out successfully. There were no untoward reactions and the patient was free from pain during the entire procedure. The cirrhotic origin of a primary cancer of the liver was demonstrated on microscopic examination in 2 cases and the diagnosis of sarcoma was clarified in a doubtful case of tumor.

Book Notices

The Diagnosis and Treatment of Acute Medical Disorders. By Francis D. Murphy, M.D., F.A.C.P., Professor and Head of the Department of Medicine, Marquette University School of Medicine, Milwaukee. Cloth. Price, $6. Pp. 503, with illustrations. Philadelphia: F. A. Davis Company, 1944.

The author has written a small but valuable book intended primarily for the general practitioner and medical student. Drawing from his more than twenty years' experience as clinical director of the Milwaukee County Hospital he has observed that, while chronic disorders are managed satisfactorily, difficulties are encountered in the treatment of the acute diseases. The subject matter is well organized and written in a style that is read with ease. The book begins with a comprehensive discussion of the acute vascular episodes, including the management of cerebral vascular crises and acute vascular occlusions. This is followed by chapters on diseases of the blood and heart, metabolic disorders, diseases of the nervous system, kidneys, lungs and acute abdominal emergencies. Chapters on the acute infections, tropical diseases and acute poisonings are presented in outline form. A final short chapter on drugs summarizes the pharmacology of digitalis and the sulfonamides. Lengthy discussions of etiology and pathology have been avoided to a great extent, while more emphasis has been placed on diagnosis and therapy. Since the form of management is based primarily on the medical experience of the author, and because of the size of the book, a bibliography is not included. Certain phases of therapy are questionable, such as endocrine therapy for cerebral vascular crises and the use of leeches in thrombophlebitis. The reviewer does not believe that hemophilia and Gaucher's disease are acute disorders.

Report upon the Work of the Miners' Phthisis Medical Bureau for the Three Years Ended 31st July, 1941. Published by Authority. Paper. Price, 8s. 6d. Pp. 46. Pretoria: Government Printer, 1944.

As heretofore, this publication contains a wealth of detail that can be appreciated only in the original. The exceptional opportunities of the bureau for continued observation of a large and relatively stable group of persons exposed to a dust of comparatively uniform composition provides one of the major sources of information on silicosis. It should always be remembered, however, that this disease varies in its local manifestations and that every detail of the conclusions is not necessarily applicable to other industries. The data demonstrate convincing evidence of the effect of a well regulated control program.

Before considering the results of the routine examinations, the report mentions several special investigations. In one based on 350 necropsies of persons previously given chest x-ray examinations it is concluded that, exclusive of chronic heart disease with pulmonary congestion, coarse miliary tuberculosis and perhaps siderosis from exposure to hematite dust, the x-ray pattern of "generalized mottling" is pathognomonic of silicosis. In persons with long industrial exposures in these mines the presence of "irregular opacities" in the apical regions with "well marked increase in linear striation" or "generalized arborization" are strongly suggestive of silicosis or tuberculosilicosis. A necropsy is reported on a hematite miner whose antemortem film had shown "generalized small mottling" but in which microscopic examination of lung sections revealed no evidence of nodular fibrosis. This is contrary to experience with hematite miners in the United States. It brings to mind the "pseudonodulation" of welders.

Previous summaries of the incidence of primary cancer of the lung in necropsies had indicated 1.27 per cent of 1,806 European males with no underground exposure, 0.74 per cent among 2,292 nonsilicotic European miners and 0.72 per cent among 1,948 silicotic miners. During the past eight years among 1,120 necropsies on deceased European miners there were 20 more cases of such tumor, 15 of them in silicotic miners and 5 in nonsilicotic ones. As the total number of men included in each category is omitted, no comparison of the current frequency is possible. However, it is concluded that "primary cancer of the lung is not more common in silicotic miners than in nonsilicotic miners."

Among 606 necropsies on native laborers examined because of pulmonary disease, 77 per cent had active tuberculosis with or without silicosis, all but 1.3 per cent being in relatively acute forms.

In the preemployment examinations of white miners, exclusion is rigorous and less than 40 per cent pass their initial tests Sixty-eight per cent of those accepted were under 25 years of age and 87 per cent under 30. "Special certificates," certifying freedom from tuberculosis, are required for any person working underground for less than one hundred hours a month, a fact which indicates the rigorous exclusion of sources of occupational infection.

Periodic examination of all regular underground employees is made at six month intervals. Detection of tuberculosis at any periodic examination immediately debars a person from underground work. On discovery of silicosis it is optional whether a miner takes an award and quits or remains at work to accept compensation later, "provided he does not thereafter develop silicosis." During each of the three years covered by the report, the number of white persons given periodic examinations was 30,465, 32,382 and 29,817 respectively. The corresponding prevalence rates for silicosis were 15.46, 15.53 and 18.67 per thousand. The "production rates" (i. e. the number of new cases developing each year) were 7.61, 7.90 and 10.05 per thousand. In 1927-1928 the production rate was 19.41, and it had decreased to the all time low of 7.03 in 1937-1938. However, it is pointed out that these figures are misleading, particularly now when the population under consideration contains an excess of men employed for relatively short periods. The "New Rand Miners," i. e. those employed since dust control was established in 1916, now constitute 83 per cent of the group currently examined, and their production rates vary from 1.76 to 3.20. Among the white miners employed previous to 1916 the corresponding annual rates now range from 44.59 to 60.96. These figures indicate pointedly *the effect of rigid selection of employees and the control of* underground environment. They also emphasize the chronicity of silicosis, since so many men employed for over twenty-five years are still developing their first signs of the disease. The average duration of employment of cases first detected with silicosis in 1940-1941 was 9¾ years, as contrasted with 19½ years in 1922-1923. The effect of control has been to double the time required to produce the disease. As the result of improvements in the drills, these machines now produce a great deal less dust and the special rates for drill operators have correspondingly decreased. Whereas in 1929-1932 drillers developed four times as much silicosis as nondrillers, their current rates are essentially the same as those for other underground employees.

The data on progression of silicosis are somewhat confusing because it is not clear whether all or only a part of the cases under discussion are still under exposure. However, the figures do indicate that progression is dependent on the amount of dust retained within the lungs at the time exposure ceases and the presence or absence of associated tuberculosis. In the absence of such infection cessation of exposure often results in prolonged and apparently indefinite arrest of the silicosis. This leads to the present conclusion that, regardless of economic considerations, miners should be urged to seek other occupations on first detection of evidence of silicosis.

The continued effort to eradicate tuberculosis has yielded returns and today this complication, which accounts for so much of the disability in the silicotic, develops rarely. During the three year period of the report there were only 46 new cases of tuberculosis not previously detected in this group of some 29,000 to 32,000 white miners. Ten of them made their first appearance as the combined lesion, "tuberculosis with silicosis," 7 in men continuing to work underground after notification of silicosis and 3 in persons with no previous evidence of silicotic fibrosis. The other 36 cases appeared as uncomplicated tuberculosis, although in some instances silicotic reaction was subsequently manifest after a variable period. In each of these years the annual production rates per thousand for "tuberculosis with silicosis" were 0.16, 0.12 and 0.03, and those for simple tuberculosis were 1.19, 0.65 and 0.44. The "Old Rand Miners," whose employment dates back to the days before dust control, still continue to develop five to seven times as much tuberculosis as the more carefully selected group of more recent employees.

Reexamination of beneficiaries under compensation who are no longer exposed to dust revealed that some who left the mines when notified over twenty-five years ago have experienced no progression of silicosis. Only about 27 per cent have advanced from one to successive stages of the disease in the past triennium, in three fourths of the cases without the intervention of tuberculosis.

Native laborers, who constitute the largest part of the working force, also receive frequent physical examinations. The cost has prevented general use of the x-rays and the reason is apparent when one considers the number employed in each of these three years, 315,742, 328,506 and 359,710 respectively. Besides preemployment and discharge examinations any native found to have lost 5 or 6 pounds in weight on a routine check every six weeks is given at least a physical examination, and after five years of service all are checked routinely every three months. Among this group the incidence rate for silicosis is only about 2 per thousand; for tuberculosis in all forms it now runs about 3.3 to 3.5 per thousand. The need is stressed for routine x-ray examinations of all natives to check such development. The low silicosis rate for natives is due to the fact that their periods of employment are much shorter than for white miners.

Clinical Evaluation of the Rehabilitation of the Tuberculous: Experience at Altro Work Shops 1915-1939. By Louis E Siltzbach, M.D., Chest Physician, Committee for the Care of the Jewish Tuberculous, Inc., New York. Cloth. Pp. 70, with 10 illustrations. New York: National Tuberculosis Association, 1944.

In seventy well printed and nicely bound pages Dr. Siltzbach has presented in an admirable manner a practical demonstration of the effectiveness of rehabilitating tuberculous patients. He describes the Altro Workshop, which opened its doors in June 1915 for the employment of tuberculous patients as a part of their rehabilitation. This workshop is engaged in the manufacture of washable garments for hospitals, health organizations and commercial establishments. Just now a large part of its output consists of cotton uniforms for the Red Cross and the government services.

Applicants between the ages of 16 and 55 are eligible, without regard to sex, marital status, race, color or creed. Patients are accepted from all institutions and from public and voluntary agencies as well as from private physicians. They are admitted to begin on part time work. It is preferred that their disease be classified as arrested before work is begun. Some patients are still receiving artificial pneumothorax while they are being rehabilitated. The workshop also receives a few persons who need permanent, sheltered employment. Some of these individuals actually have tubercle bacilli in the sputum but are able to work under close medical supervision. All of the persons employed in this workshop are observed with extreme care and at frequent intervals by the medical staff, and the work they do as well as the number of hours per day is prescribed by physicians.

Usually patients are not discharged until they are able to work on a full time basis. After discharge, a close follow-up is made to be sure that their lesions remain well under control. This is for the remainder of their lives. Of course those with tubercle bacilli in the sputum are never discharged to be employed in outside organizations.

Between 1915 and 1939, 964 patients were admitted to this workshop and were followed to the closing date of the survey, July 1941. Ninety-seven per cent of the workers were traced five years and 92 per cent ten years. Four out of five of the workers had moderately or far advanced lesions on entrance to the workshop; in 63 per cent the lesions were arrested. At the end of ten years after discharge, 87 per cent of the workers with minimal lesions and 86 per cent of those with moderately advanced lesions survived. Of those with far advanced lesions only 63 per cent survived. Seventy-two per cent were able to work full time on the fifth anniversary of their discharge, on the tenth anniversary 62 per cent. Five hundred and fifty-two of the workers completed the course and were graduated as apparently fully rehabilitated, 89 per cent of whom were working or were able to work on a full time basis on the fifth anniversary and 85 per cent on the tenth anniversary from discharge. This is a splendid accomplishment and should lead the way to the establishment of many more similar institutions.

The Embryology of Behavior: The Beginnings of the Human Mind. By Arnold Gesell, M.D., Ph.D., Sc.D. In collaboration with Catherine S. Amatruda, M.D. Cloth. Price, $5. Pp. 289, with illustrations. New York & London: Harper & Brothers, 1945.

This book is a description of the body and mind "in the making." The author's assumption is that, as the soma takes shape, the psyche takes shape: "we are dealing with a single developmental morphology." In the first nine chapters the beginnings of behavior are traced. Here an enormous literature is digested and organized into a fascinating account of the development of the embryo and of the structure and behavior of the fetus. The primitive motor system, breathing, behavior and muscle tone are discussed. The concept of electrotonic integration and the interdependence of structure and function are elaborated skilfully. Two chapters are devoted to observations of the behavior of prematurely born infants. The subjects were infants cared for in the station for prematurely born infants at the New York world's fair. Here the methods of observing and recording infant behavior already made familiar in the author's previously published works were utilized to give a vivid and exact description of the behavior patterns of these youngest infants. A chapter on the cycle of sleep gives in great detail observations on the development of the normal diurnal sleep cycle. In the first chapter the universality of the laws of physical and biologic science that underlie the possibility of "bringing into unitary progressive relationship both living and nonliving systems" is discussed. Numerous photographs delineate the behavior patterns of prematurely born infants. This carefully written book condenses for physicians and students of behavior much of present day knowledge of the beginnings of behavior. The new work of the author pertaining to the prematurely born is of a high order of importance. The concept of behavior as an aspect of the functioning of a total organism, understandable in terms of its immaturity or maturity, is a valuable one for medical students to grasp adequately. While the publishers would like us to believe that this book is one that could be read by prospective parents, it is much more suitable for the medical student, pediatrician and students of behavior than for lay readers. It is certainly one of the best of the many excellent publications by Dr. Gesell.

Atlas of Dental and Oral Pathology. By James B. Mann, Colonel Dental Corps, U. S. Army; J. E. Ash, Colonel Medical Corps, U. S. Army, and Joseph L. Bernier, Major Dental Corps, U. S. Army. Prepared at the Army Institute of Pathology of the Army Medical Museum, Office of the Surgeon General, Washington, D. C. From Material in the Registry of Dental and Oral Pathology. Third edition revised by Henry M. Goldman, Lieutenant, Dental Corps, U. S. Army. Cloth. Price, $5. Pp. 310, with illustrations. Chicago: American Dental Association, 1944.

The revised edition of this well known atlas gives a complete illustration of dental and oral pathologic conditions. Although attention is focused on the histopathology, photos of patients and roentgenograms are added wherever they are necessary for the understanding of the condition. The photomicrographs are, with a few exceptions, good and clear. In some instances the general view pictures under low power are not entirely satisfactory. Some of the diagrams used are too primitive. The text accompanying the illustrations is excellent in its brevity and clarity. Every dentist and oral surgeon will study this atlas to great advantage and will want to have it in his library. The physician will find it to be a useful reference book.

A Source-Book of Biological Names and Terms. By Edmund C. Jaeger. Cloth. Price, $3.50. Pp. 256, with 96 illustrations by Merle Gish and the Author. Springfield, Illinois & Baltimore: Charles C Thomas, 1944.

This work includes 12,000 elements from which scientific biologic names and terms are made. With them are the Greek, Latin or other origins and some concise definitions. The book should be most useful to students of biology.

Old Age: Some Practical Points in Geriatrics. By Trevor H Howell, M.R.C.P., Captain, R. A. M. C. Boards. Price, 4s. 6d. Pp. 50. London: H. K. Lewis & Co., Ltd., 1944.

This work represents a collection of reprints from a number of British medical periodicals. It is exactly what the title purports it to be—a collection of clinical points by an experienced practitioner.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HEALTH FACILITIES AND LIABILITIES IN SUMMER CAMPS

To the Editor:—I am a member of a board regulating activities at a summer camp for children. We are about to erect an infirmary, and in that connection I am debating the wisdom of confining sick children there or sending them home, particularly those who have acute upper respiratory infections who might be ill for two or three days or, as occasionally happens, might develop complications. What legal difficulties might develop if a sick child is cared for in the infirmary and something unforeseen should occur? Would this legal liability apply equally to the scholarship camper (nonpaying) and the paying camper? I should like to know how other camps caring for about 100 to 150 campers weekly have approached this problem. Any information you can give me would be appreciated.

M.D., Ohio.

ANSWER.—The question is in two parts, medical and legal. Each is answered separately.

1. Summer camps, except those specifically established for the care of sick or handicapped children, should be places where well children can enjoy a full measure of activity. They are not places for prolonged care of ill children. The camp infirmary, except in rare instances, is not usually a suitable place to care for sick children beyond a short time. A camp should have at least a dispensary and a few beds for emergencies; more important, and usually neglected, is that competent personnel shall be available for the use of facilities. The erection of an infirmary is only a beginning in the solution of the problem here posed. Provision must be made for resident medical care or availability from nearby with genuine ease and promptness, plus nursing care if required.

Children mildly ill for a day or two may often return to full participation in camp life and can safely be observed in an infirmary, but if illness is severe or prolonged the child should be removed to home or to a nearby hospital. Authorization for such action may be obtained from parents in advance or as the occasion arises and should include clear statement as to responsibility for expense incurred. Communicable diseases are usually at a minimum in the summer; nevertheless the possibility of their occurrence should be considered. The infirmary will be less likely to prove a center of contagion if it is built so that one or at most two persons occupy a cubicle. Construction of such an infirmary need not be elaborate, but it should be a building finished with plaster and paint and glass windows; rough open construction is difficult to keep clean.

2. The courts, as far as the reported court decisions indicate, have never been called on to pass on legal liability in this particular connection. In the absence of any specific agreement between camp authorities regarding the medical care or attention to be provided for a particular child, on general legal principles there would seem to be no basis for imposing a different degree of care on the part of the camp with respect to a "paying" camper and a "nonpaying" or "scholarship" camper, and the law would seem to impose the same degree of care and solicitude on camp authorities with respect to each type of camper. An answer concerning the legal liability that might develop "if a sick child is cared for in the infirmary and something unforeseen should occur" must be extremely general. As far as is here material, the foundation of legal liability rests either on negligence or on the breach of a promise to do a particular thing. In the absence, then, of a specific undertaking to do certain things, liability must rest on negligence—that is, on a failure to do what an ordinarily reasonable man would do under similar circumstances. Neither the camp nor the physician is an insurer of good results. It is not responsible for bad results—presumably the "something unforeseen" referred to in the question—unless that bad result is causally related to a responsible negligence. Whether or not the camp was negligent is a question of fact to be determined in the light of the evidence in each case.

PRESERVATION OF BREAST MILK

To the Editor:—What is the accepted method of preserving breast milk in small quantities for hospital use? H. A. Raube, M.D., Beloit, Wis.

ANSWER.—Breast milk can be kept as long as a year by freezing. For small quantities, pasteurize the milk and strain through sterile gauze into a sterile 4 ounce nursing bottle; cap immediately. When cold, place in the freezing chamber of an ordinary electric refrigerator. About ten hours is required to freeze the milk solid when the gage is set to freeze ice cubes. Bottles holding more than 4 ounces will break during freezing. The frozen milk may be kept in the coils or the freezing chamber of the ice box; however, a "deep freeze" storage chamber is preferable if one can be obtained. The milk should be repasteurized before using, and a check of the condition of the supply should be occasionally made by culturing a sample for the presence of bacteria. Milk that has thawed for any length of time should not be used.

PATCH TESTS FOR OCCUPATIONAL DERMATOSES

To the Editor:—What is the diagnostic importance of the skin patch test in occupational contact dermatoses? What is the relationship of the patch test to the history and to the clinical and laboratory examination in cases of occupational dermatoses? M.D., Pennsylvania.

ANSWER.—The patch test is an important and valuable criterion in the diagnosis of allergic occupational dermatitis. In industry it is a comparatively easy matter to learn all of the allergenic substances which come in contact with the worker in his occupational environment. Therefore, obtaining these substances and performing patch tests with them is not difficult.

The patch test should be employed only by physicians familiar with the technic of its application and experienced in reading and evaluating the reactions.

Patch tests should not be performed with primary skin irritants, i. e. those which will inflame all skins. If it is necessary to ascertain whether a worker is hypersensitive to the action of primary skin irritants, patch tests can be performed with such dilutions of the chemical as will not affect the normal skin. Such dilutions have been ascertained for many chemicals (Schwartz, Louis, and Tulipan, Louis: A Textbook of Occupational Diseases of the Skin, Philadelphia, Lea & Febiger, 1939, pp. 53-61).

The patch test is not the sole criterion on which the diagnosis of occupational dermatitis is made, other criteria being the occupational history, the site of the eruption, its appearance and differential diagnostic data. The subject of patch testing is broad. For further discussions the following references are suggested:

ENCEPHALOGRAM IN DIAGNOSIS OF IMBECILITY OR ENCEPHALITIS

To the Editor:—A boy now 6 years of age has a mental age of about 18 months. He had an apparently normal first year according to the parents and the family doctor; he walked well at 15 months. Snapshots taken during his first year certainly tend to confirm the impression of normality, his expression being bright and alert, in striking contrast to that at present. Sometime in his second year mental development stopped. Skeletal x-rays show normal ossification. During his second winter he had repeated severe upper respiratory infections, in the course of one of which he was extremely drowsy for an entire week. If he had had some form of encephalitis at that time would an encephalogram made now establish such a diagnosis? The parents are expecting a second child, and any light on the situation might serve to relieve their anxiety. They have been told at the institution where the child is an inmate that an encephalogram would be a foolish waste of time and money.

Elizabeth Roylance Daley, M.D., Bronxville, N. Y.

ANSWER.—An encephalogram would not furnish information which would alter the therapy or improve the prognosis in this case; from this aspect it would be a waste of time and money. However, it probably would furnish evidence of any gross atrophy of the brain. Such pathologic changes, if present, would presumably be acquired and not genetic in origin—a matter of moment to the parents. The examination would not disclose the agent responsible for such pathologic changes; the history is suggestive of encephalitis. An electroencephalogram might give additional information of localized acquired pathologic changes.

THIAMINE HYDROCHLORIDE FOR PAINS IN ARMS DURING PREGNANCY

To the Editor:—In the February 17 issue of The Journal there was an inquiry by O. G. Mills of Oshawa, Ont., regarding pains in the arms during late pregnancy. The answer stated that the administration of vitamins and calcium is of no value. I wish to disagree because I have found in many cases that the use of 10 to 30 mg. of thiamine hydrochloride taken orally stopped the pains and the numbness frequently both in the arms and in the legs.

NEW YORK

A consideration of the value of castration in relation to cancer of the breast is one which periodically has presented itself to the medical profession for a period of fifty-five years since its suggestion by Schinzinger in 1889. The work of Huggins in cases of cancer of the prostate has again brought up for review the subject of castration in cancer of the breast. It may be recalled in Huggins' work that the total effect of castration of the male was not obtained when castration was carried out by x-rays. He obtained his effects by surgical castration, and this is the reason for bringing up at this time a reconsideration of the subject of x-ray castration versus surgical castration.

This study represents a review of all the patients with carcinoma of the breast who have been castrated with surgery or radiation in a period of eighteen years at the Memorial Hospital in New York City. All the women considered in this series for effect of castration on the course of mammary cancer are selected carefully to include only those who have functioning ovaries. Patients are included up to 55 years if they were having regular menstrual periods. If those under 45 years have had a hysterectomy or ceased menstruation for any reason, they were excluded from this series.

Often the castration was performed for reasons unrelated to the mammary cancer, such as menorrhagia caused by fibromyomas of the uterus or for a carcinoma of the cervix. The total number castrated was 342: 335 women and 7 men. Of the women 31 were surgically castrated and 304 received high voltage x-radiation or intrauterine radium in sufficient amount to stop the ovarian function.

From the Breast Department of the Memorial Hospital.

Part of the expense of the follow-up work, as well as certain funds for clinical research, were furnished by the Katherine Straub Cancer Fund.

Read before the Section on Surgery, General and Abdominal, at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 15, 1944.

On account of the length of the paper, the entire review of the literature together with the bibliography and other matter is deleted but will be found in the authors' reprints.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

REVIEW OF LITERATURE

The experimental literature on the subject of castration in animals is enormous and, unfortunately, most contradictory. With the exception of a few outstanding points in the experimental field, a review of the work of the experimentalists leaves one somewhat unconvinced.

For the sake of estimating the value of castration we considered the results as susceptible of being placed in one of three groups: (1) improved by castration, (2) uncertain as to improvement by castration, (3) not improved by castration.

The criteria for consideration as to improvement were (1) the presence of axillary nodes, (2) pregnancy, (3) age of the patient, (4) grade of malignancy of the tumor, (5) duration of life following castration and (6) course of the disease following castration.

We hold that it is improper to consider that the patient received any benefits by castration if the course of the disease was not materially changed or if the patient died within a two year period following castration. However, if the patient lived more than two years after bone or soft part metastasis we then classified that patient as having received benefit from castration, provided the patient had no axillary involvement at the time of the operation. In other words, if the patient had no axillary involvement that patient had at least a 75 per cent chance of cure anyway. If the patient has had only a year or a year and one-half following castration when there appeared to be some improvement in the clinical course, that patient was placed in the group "uncertain as to improvement."

Analysis of the 335 women castrated reveals that of the 304 castrated by x-rays 47, or 15 per cent, according to our criteria, were improved, 57, or 19 per cent, were in the group uncertain as to improvement and 200, or 66 per cent, were not improved by castration. Of the 31 patients surgically castrated 4, or 13 per cent, were in the improved group. 7, or 23 per cent, were in the uncertain group and 20, or 64 per cent, were in the unimproved group.

It will be noted from the study of table 2 that women castrated by surgery or by irradiation methods appear to have approximately the same result as far as improvement goes, namely 15 and 13 per cent. Those definitely not improved were 66 per cent by x-rays and 64 per cent by surgical castration. It is obvious that, in order for us to make this comparison a proper comparison, we should have a greater number of surgical castrates. The analysis of improved cases according to age groups shows that among the 51 improved patients in the entire series 33, or 62 per cent, were 40 years of age or less.

During the course of this analysis we have written to twelve outstanding radiation therapists for their opinions on the value of castration in mammary cancer,

and the average of their combined opinions was that castration was of value in approximately 20 per cent of the cases. In contrast to this opinion our 304 patients castrated by the x-rays gave a 15 per cent improvement. However, it is quite possible that of the "uncertain" group some would eventually be added to the improved group, making the 15 per cent a little higher. The same holds true with the 13 per cent improvement in the surgical group. It should be here stated that an exact evaluation of improvement is a very difficult matter for one to determine. Owing to the vagaries of the cancerous diseases and because of the human soil in which the cancer grows and as the result of many other factors, evaluation of castration will always remain out of the realm of exact scientific evaluation. On the other hand, one may obtain a general idea of the value of castration on purely clinical grounds. Unfortunately one cannot predict which case will receive benefits and which case will not. From our studies it would appear that the sum total of improvement amounts to approximately 13 to 15 per cent in women. It should be here repeated that this applies to women who still menstruate and does not include those who are past the menopause. A study of the value of castration in women past the menopause should be made.

It has been of some interest to note that approximately one third of the patients castrated surgically showed metastatic disease present in the ovaries at the time of microscopic study. Unquestionably there are instances in which a patient castrates herself by metastatic disease. In 1 of the most striking instances in our experience, reported by Hoffman in the *Surgical Clinics of North America,* self castration was responsible for the spectacular change in the clinical course of the disease. The patient was a private patient of one of us and was rapidly losing ground from local recurrence about the operative wound and from metastatic disease including large nodules on the scalp as well as pelvic bone metastasis. Her clinical course changed, she gained 50 pounds (23 Kg.) and had a complete improvement in general health, which was maintained for about a year and a half. She then started downward, death coming within six months. At autopsy both ovaries were completely replaced by metastatic disease. This entire subject of castration must be considered also in the light of what may take place in the adrenals following castration. In laboratory

TABLE 2.—*Castration of 335 Women with Carcinoma of the Breast*

Course of Disease	Radiation		Surgical Castration	
	Number	Per Cent	Number	Per Cent
Improved	47	15.4	4	12.9
Uncertain as to improvement	57	18.8	7	22 6
Not improved	200	65.8	20	64.5
Total	304	100.0	31	100.0

animals there is evidence that the ovarian function is taken over by the adrenals, and it is possible that this same effect may take place following oophorectomy in the human being, which may help to explain the temporary nature of the improvement that takes place in castrates.

We recognize that castration is a very disturbing procedure both mentally and physically for any young woman. It upsets her career as a woman, so that the procedure should not be taken lightly. On the other hand, if it saves lives it is worth the ill effects. In our clinic we have attempted to make a sharp line of indication for castration. For example, we castrate by x-rays any young woman with breast cancer which involves the axilla or which has metastasized to a distant part or has recurred locally. We do this because we recognize that any such case is a desperate one. We do not castrate a young woman if at operation a study of the axillary contents proves it to be negative for metastasis and, on the other hand, if the patient has passed her menopause we do not give a castration dose even though the axilla is involved. However, this problem must be further studied. Unquestionably the function of the ovary does not cease at once with the cessation of menstruation and it is highly probable that some women will receive benefit by ovarian irradiation, even though the menopause has been passed.

TABLE 3.—*Results in 304 Cases in Which Castration Was Done by X-Rays or Radium*

Indication	Course of Disease			
	Improved	Possibly Improved	Not Improved	Totals
Bone metastases	28	27	126	181
Primary castration	9	10	5	24

Local recurrence	6	4	16	26
Carcinoma of cervix	0	0	4	4
Menorrhagia from fibroids	1	7	24	32
Following pregnancy	1	3	7	11
Metastases to ovaries	0	3	8	11
Total	47	57	200	304

The patients receiving high voltage x-ray treatment to the pelvis are analyzed to show why castration was carried out. A considerable number had this treatment for pelvic complications at a time when the mammary cancer was assumed to be under control; consequently, although patients may be alive many years later, the result will be given here as "no improvement." Table 3 analyzes the 304 cases in which castration was done by high voltage x-rays or radium, according to the reason for this treatment. Each group will be analyzed separately, with illustrative cases.

CASTRATION FOR BONE METASTASIS

By far the largest group of young patients with carcinoma of the breast had castration with high voltage x-rays for the treatment of bone metastasis incidental to the treatment of metastasis in the pelvic bones. The total number was 181. Of this total 126, or 70 per cent, had no appreciable improvement attributable to castration. Fifty-nine, or 47 per cent, of those unimproved lived only six months or less after castration, and 45, or 36 per cent, lived from six to twelve months. Only 22, or 17 per cent, lived twelve months or over, and these were not improved clinically, having continued extension of the bone metastases and extreme disability.

A small number, 28, or 15 per cent, had definite improvement following the administration of a castrating dose of radiation therapy to the pelvic region, and the duration of life was over five years in 5 patients, from four to five years in 1, from three to four years in 5 and from two to three years in 17. These patients had well defined clinical improvement with relief of pain, some with radiologic evidence of healing of the bone, and in some instances life was prolonged in spite of the advanced stage of the carcinoma. One patient is still living and well today eight years after roentgen castration whose radical amputation for a

grade 3 carcinoma of the breast was carried out ten years ago. She had bone metastasis two years after the treatment for a primary operable carcinoma at the age of 36 years. Another patient who lived six years after castration died of a coronary occlusion. Two other patients are still well with no demonstrable carcinoma two years after castration.

An equal percentage, 15, or 27 patients, who were clinically improved after roentgen castration for bone metastasis may possibly have received this benefit from castration. A number of these patients are still living and have no symptoms. The duration of life was over five years in 3 patients (2 still living and well), 3 years in 1, from two to three years in 2, from eighteen to twenty-four months in 6 and from twelve to eighteen months in 15.

PRIMARY CASTRATION

This group is termed primary castration because a cycle of high voltage roentgen therapy was used as part of the initial treatment of the mammary cancer when the patients applied for treatment. The patients included in this group were young women, 67 per cent 40 years of age or less, who either had advanced operable carcinoma with axillary lymph node involvement or inoperable carcinoma or had been maltreated for operable carcinoma, such as, for example, by repeated local excision of the cancer in the breast.

Although not a large group, 24 in all, 37 per cent of these patients showed improvement beyond the expected history of the individual case, having lived three and one-half to fourteen years after castration. An additional 41 per cent were possibly benefited by this treatment; that is, 78 per cent of the total showed clinical improvement which may or may not be attributed to x-ray castration. This is a small group and the patients were selected for this in a rather desperate chance, as may be judged by the following case:

A woman aged 31, who applied to the Memorial Hospital for treatment on March 9, 1938, gave a one year history of an inverted nipple and a lump in the right breast. Because of her age and lack of axillary involvement, several attempts were made without success to prove the diagnosis by aspiration biopsy and excision of skin nodules. A short cycle of high voltage x-radiation was given to the breast and three weeks later a simple mastectomy was performed. The pathologist's report was infiltrating duct carcinoma, grade 3, with metastases in the skin. Within a short time a mass appeared in the opposite breast and a month after the first operation a left radical mastectomy was done, removing the same type of carcinoma with metastases in the axillary nodes. Within the next two months, right axillary nodes became enlarged and the tissue from an axillary dissection contained seven nodes which the pathologist reported as replaced by metastatic carcinoma, grade 4.

High voltage roentgen therapy had been given to the pelvis in March of 1938 at the time of the first treatment (therefore termed "primary castration") and a heavier cycle was given in September of 1938 after the three operations described. Postoperative roentgen therapy was also given locally to the axillas and chest wall. Another cycle of pelvic x-radiation was given in 1941 for bone pain. The patient was living and well with no evidence of recurrence or metastasis when last seen, Dec. 2, 1943, over five years after castration and initial treatment.

LUNG OR LIVER METASTASES

Fifteen patients with carcinoma of the breast metastasizing to the lungs or liver or both received pelvic x-radiation in large enough amounts to produce cessation of the menses. This was given as a last resort to patients who seemed to require some form of palliative treatment. Two patients seem to have improved after castration in spite of radiographic evidence of pulmonary metastases. They are still living five years and nine years after castration, though symptoms of metastases have recurred. Three other patients may have had their lives prolonged by the castration produced by x-radiation. They had relief of symptoms and lived more than a year after diagnosis of lung or liver metastases and castration. The remaining 10 had no change in the usual rapid downhill course, with death in a few months.

CARCINOMA OF CERVIX

Four patients with carcinoma of the breast developed carcinoma of the cervix uteri. All were diagnosed by biopsy as having epidermoid carcinoma, which was a second primary carcinoma in each instance. The time interval from treatment of the mammary cancer until development of the cancer of the cervix was one and one-half years, eight months, six years and five years, respectively. One patient lived nearly three years after treatment of the second cancer and died of pelvic extension of the carcinoma of the cervix. Her mammary cancer had not recurred, although it was nearly nine years since she had had a radical mastectomy for a "low grade infiltrating tubular carcinoma of the duct and foci of sweat gland adenoma and sclerosing abortive adenomatosis, somewhat atypical and suggestive of further foci of neoplastic growth." She was 44 years of age at that time, and there was no axillary node involvement. In none of these cases did the castration, in our opinion, affect the course of the mammary carcinoma.

MENORRHAGIA CAUSED BY FIBROMYOMAS OF UTERUS

A total of 32 patients treated for carcinoma of the breast had radiation castration for menorrhagia caused by fibromyomas of the uterus at some time in the period of treatment or observation. Only 1 of these, or 3 per cent, is judged to have had any benefit from the cessation of ovarian stimulation:

This patient, L. V., aged 36, had an operable carcinoma after local excision elsewhere five weeks before. She had a radical mastectomy performed, and the axillary lymph nodes contained metastases. Heavy postoperative external radiation was given with the radium pack locally. The following year she had local recurrences treated successfully with more external radiation. Two years later pelvic x-radiation was given because of the presence of large fibromyomas of the uterus and menorrhagia. She was improved after this and required no further treatment until six and one-half years later, when there was bone destruction in the spine and extension of carcinoma in the cervical lymph nodes. She survived another year, a total of eleven years after the original treatment and nearly eight years after castration.

The 7 patients (22 per cent of 32 treated for fibromyomas) who are listed as possibly improved had treatment within a short time after treatment of the mammary cancer and are alive several years later (two to ten years) or lived for several years after castration, dying of carcinoma.

Unimproved by castration in this series were 24 patients, or 75 per cent. Most patients lived four or more years after castration but, because the mammary cancer was apparently adequately treated, the course is considered to be uninfluenced by the ovarian dysfunction.

CASTRATION FOLLOWING PREGNANCY

Twelve patients had pregnancy complicating the course of carcinoma of the breast. The pregnancy occurred either with the primary carcinoma or follow-

ing the treatment. Eleven patients were castrated with high voltage x-radiation after the termination of the pregnancy by abortion or delivery. The twelfth had surgical castration and is included in that group in the tables. This case is very interesting and may be reviewed briefly:

S. Z., aged 34, who was admitted to the Memorial Hospital Dec. 29, 1928 with a history of a caked breast following the weaning of her youngest child two years before, had noticed a swelling the size of a hen's egg in her left armpit in October 1928 and redness and swelling beneath the left clavicle. Her local physician gave her "baking treatment" and the swelling subsided somewhat. When examined she was found to have extensive involvement of the left breast, chest wall, axilla and supraclavicular region with a carcinoma which was hopelessly inoperable. She was treated with high voltage roentgen therapy combined with radium pack and radon gold seeds to the breast, axilla and lower neck, with some regression of the tumor. In 1930 she was found to have a large pelvic mass, and in February 1930 a laparotomy was performed and the uterus, both ovaries and oviducts were removed. The uterus contained an embryo 3 cm. long, and one ovary was destroyed by a tumor which was diagnosed as metastatic tubular carcinoma of the breast. On March 16, 1931 a simple mastectomy was performed because of an increasing mass, and the tumor, 4.75 by 2.0 by 3.0 cm., was a cellular bulky adenocarcinoma. The patient was well for over a year but developed local recurrences on the chest wall extending to the opposite breast and died Nov. 20, 1932, almost four years after primary treatment and two years and eight months after surgical castration.

Of the 11 patients who had castration doses of radiation to the pelvis following pregnancy, 7 lived less than a year, during which time there was rapid progression of the mammary carcinoma. Three had longer survival, which we think may have been influenced by the castration, since further disease had developed, indicating lack of cure. The survival following castration was two years, four and one-half years and eight years, respectively.

One patient is listed as definitely improved by castrating effect, since she had an early pregnancy during the course of preoperative radiation therapy. Radical mastectomy proved the presence of carcinoma with axillary node metastases. Postoperative pelvic x-ray therapy caused abortion and castration. She survived three years longer.

TABLE 4.—*Results of Orchiectomy in 6 Cases*

Case	Clinical Classification	Mammary History	Pathologic Condition	Physical Findings on Admission	Treatment	X-Ray Studies	Date of Castration	Pathologic Report on Testes	Course
1. M. S. Age 72 White, Italian-Catholic. Married, 2 children. Date of admission, 4/28/41	Primary inoperable, left	Ulceration of nipple for 4 months; mass 5×6×2 cm.; axillary nodes	2/9/42: formal biopsy; infiltrating carcinoma, grade 2	Areola and nipple destroyed; stayed away for 9 months after mastectomy was suggested	None except orchiectomy	4/30/41: negative 1/30/42: widespread 5/28/42: rib fractures healed 6/17/42: calcification 6/22/42} continued 8/24/42} improvement 3/17/44: no change 5/25/44: ? reactivation	2/9/42	Atrophy and interstitial cell hyperplasia	Remarkable clinical regression of primary lesion with regeneration of bone; blood chemistry returned to normal; question of relapse
2. J. S. Age 75 White, English-Protestant. Married, 6 children. Date of admission, 6/10/41	Recurrent inoperable, right	Lump for 1 year, 6×4 cm.; nodes in axilla	7/1/43: infiltrating carcinoma, grade 3; node metastases, multiple	Lesion ulcerating; nodes involved	Radical mastectomy 7/1/41: estrogen 228,000 mouse units 7/23: orchiectomy 8/18/42	2/26/42: skull positive 3/27/42: ribs, spine, pelvis 6/20/42: widespread 7/17/42: increased 12/28/42: right lung increased	1/27/42	Testes slightly atrophied	Had liver cirrhosis; died at operation 1/30/43; estrogens reactivated ?
3. B. D. Age 65 White, Austrian-Jew. Married, 1 child. Date of admission, 4/13/42	Prophylactic, right	Local excision 15 years prior to axillary dissection, 2/23/42	2/23/42: infiltrating duct carcinoma, grade 3	Scar granulating; radical axillary dissection; no evidence of recurrence	Excision and axillary dissection elsewhere; irradiation postoperatively and orchiectomy	5/27/42: ? 12th D; 1-3-4 L 8/24/42: positive 12th D; 1-2-3 L	5/8/43	Atrophy, mild	Weight increase of 40 pounds; no pain; no evidence; bone regeneration by x-rays
4. A. I. Age 64 White, Irish-Catholic. Married, 1 child. Date of admission, 6/1/43. Meadowbrook Hospital	Primary operable, left	Breast lump, 3 weeks; bilateral hydrocele, 3 years	6/12/43: local excision: adenocarcinoma	Left breast lump 2 cm.; no nodes	Local excision only; axillary dissection; orchiectomy	Negative chest; no symptoms of bone metastasis	6/12/43	Testes normal	10 months after excision axilla was dissected; no metastasis
5. E. S. Age 39 White, Irish-Catholic. Married, 2 children. Date of admission, 10/15/43	Primary inoperable, right	Right breast lump 2×1.5 cm., 6 months; 8 lb. weight loss; axillary nodes, bilateral	10/18/43: aspiration biopsy; carcinoma	Lesion having skin attachment; many nodes; pain in back	Orchiectomy only	10/15/43: ribs 11/22/43: skull and pelvis 12/30/43: widespread 2/21/44: increase 3/20/44: increase	12/8/43	Testes essentially normal	Died of disease 4/4/44
6. A. P. Age 63 White, German-Catholic. Married, 2 children. Date of admission, 2/1/43	Primary inoperable, left	Left breast lump 7 months, 5×4 cm.; ulcer of nipple, slight; cutaneous nodules; mass in axilla 5×4 cm.	12/1/53: aspiration biopsy; carcinoma	Primary 5×4 and axillary mass 5×4; cutaneous nodules	Orchiectomy only	10/1/43: pulmonary, more evident on right 3/ 1/44: increase 3/31/44: decrease ? 5/24/44: pelvis positive; lung not so well defined	1/19/44	Atrophy slightly tubular; spermatogenesis noted; normal interstitial cells	Breast tumor somewhat smaller; no change in nodes; less pulmonary disease; no increase in pelvic metastases present on admission

SURGICAL CASTRATION

The 31 patients surgically castrated may be analyzed in the same way as those having radiation castration.

The first of 2 patients improved who were surgically castrated when uterine fibromyomas were removed had the operation and radium castration. The second had surgical castration less than a year after treatment of the cancer of the breast. The patient listed as possibly improved had surgical castration three years after treatment of an early carcinoma of the breast and therefore may have been well ten years later. It may be noted that none had improvement of bone metastases

except the one who also had ovarian metastases and is therefore listed under that heading.

The 7 patients considered to have possibly benefited by castration are all living and well at this time but were too recently castrated to have scientific significance.

THE STUDY ON ORCHIECTOMY FOR BREAST CARCINOMA

In 1942 Farrow and Woodard,[21] working in our Breast Department, were led to observe the effects of the administration of androgens and estrogens on the serum calcium in patients with skeletal metastases from breast cancer. Impressed by the favorable results obtained in the retardation of the growth of osseous metastases in mammary carcinoma by radiation castration, they studied the effects of "Chemical castration" by the injections of testosterone propionate. They found that the 3 patients who received such therapy had increased blood calcium levels as well as an increased output of calcium in the urine. The chemical changes were accompanied by clinical and roentgenographic evidence of increased activity in the metastatic disease in bone. They inferred that the ability of the male and female sex hormones to cause hypercalcemia in such cases was due to the stimulation by the hormones.

TABLE 5.—*Results in 31 Cases of Surgical Castration*

Indication	Course of Disease: Improved	Possible Improvement	Not Improved	Totals
Bone metastases	0	2	4	6
Primary castration	0	4	3	7
Ovarian metastases	2	0	6	8
Primary carcinoma or sarcoma of ovary	0	0	2	2
Fibromyomas of uterus	2	1	4	7
Recurrent carcinoma of breast	0	0	1	1
	4 (13%)	7	20	31

The use of androgens for such therapy, the numerous recent favorable results reported in treating inoperable and metastatic carcinoma produced by x-ray castration and the older reports on surgical castration for inoperable breast cancer in females suggested that a similar procedure be tried in males. Farrow and Adair[22] observed the results of orchiectomy on metastatic osseous metastases. Four months later the case was reported. At that time only the clinical effects could be interpreted. That case is now reported fully, together with 5 additional cases (table 4).

At the time at which orchiectomy was performed the clinical classification of these six cases was primary operable 1, recurrent inoperable 1, primary inoperable 3 and prophylactic 1.

The consent for orchiectomy, even in elderly men with advanced breast cancer, was most difficult to obtain. It appears to be a triumph of medical persuasion to obtain permission for this operation. Even 1 elderly man with intense pain from osseous metastases was unwilling to undergo castration.

The effects of orchiectomy may be illustrated by the following abstract on the first case history:

M. S., aged 72 when he was admitted to the Breast Clinic of Memorial Hospital on April 28, 1941, had a mass in his left breast which had ulcerated four months prior to his admission to the clinic.

The patient was fairly well preserved. The physical examination revealed a sloughing ulceration which had destroyed the left nipple and areola. There was a crater measuring 3 cm. in diameter, beneath which was a stony hard mass about 5 cm. in diameter. The tumor was fixed to the chest wall. There were several small axillary nodes.

It was difficult to obtain the patient's cooperation. He did not return for any treatment until February 1942. At this time the lesion was still movable over the chest wall but the ulceration had increased (fig. 1). In addition to the original findings, he had pain in the lumbar spine and pelvis. There were numerous areas of osteolytic bone destruction involving especially the ribs (fig. 2), fourth lumbar vertebrae, the pelvis and the upper femurs.

A formal incisional biopsy was obtained at the time of bilateral orchiectomy. The pathologic report was "infiltrating mammary carcinoma, grade 2." There was decided regression in the primary lesion, the ulceration having healed and the tumor regressing much in size. In March 1942 the lesion of the left breast appeared only as a scar (fig. 3). The patient experienced considerable relief from pain within two weeks after orchiectomy. There was regression in the osteolytic areas with metastases, and the pathologic fractures of the ribs noted in the initial film had healed (fig. 4).

FIG. 1.—Ulceration and destruction of the left nipple and areola by mammary carcinoma in a male breast.

The case represents a satisfactory and unusual regression for a two and a half year period of a primary cancer of the male breast which had widely metastasized to bone.

We may summarize the clinical results of this study by stating that bilateral orchiectomy is responsible for the regression of the primary lesion in 2 instances, quite strikingly in 1 of the cases. It has possibly prevented recurrence in the primary operable case treated

21. Farrow, J. H., and Woodard, H. Q.: Influence of Androgenic and Estrogenic Substances on Serum Calcium in Cases of Skeletal Metastases from Mammary Cancer, J. A. M. A. **118**: 339 (Jan 31) 1942.
22. Farrow, J. H., and Adair, F. E.: Science **95**: 654, 1942.

only by local excision and may have prevented local recurrence in 1 other instance. The procedure has caused regression and repair in the secondary deposits in bone as well as in lung. The clinical regressions in this study compared with those reported for inoperable and metastatic carcinoma of the prostate have had the same dramatic cessation of metastatic bone pain as well as the spectacular immediate feeling of well-being. The clinical improvement has been most striking and as permanent. In fact, we think this procedure for male breast cancer at least parallels the results of orchiectomy for the advanced cases of prostatic cancer. One patient with advanced cancer has now survived two years and four months after castration, 1 thirteen months. Both are in excellent states of nutrition and are free from pain. Two have lived for nearly six months with

Fig. 3.—Resulting cicatrization of the primary mammary tumor two years and four months after orchiectomy.

regression of their disease, giving clinical promise of survival for equally long periods. Two of the patients have shown definite reparative changes in metastatic deposits in bone, while 1 with a solitary area of bone involvement has shown no evidence of progression of the disease, nor have other areas developed since castration. The latter patient has had regression in the extent of his pulmonary metastases. In 2 instances the primary lesions have greatly diminished. The patient with longest survival shows only a cicatrix of what was formerly a large ulcerating carcinoma; another patient shows regression in the ulceration and in the cutaneous nodules. The latter patient has not survived long enough to make it possible to evaluate the ultimate effect of orchiectomy on the breast tumor.

We must call attention to the relatively small number of male patients with mammary cancer available for such a study. However, the value of this type of therapy is most striking. The duration of the good effects yet remains to be determined. From our studies it would appear that the young men with breast cancer do not get the same spectacular improvement that the elderly men obtained from castration.

SUMMARY

It would appear that x-ray castration and surgical castration give improvements in approximately 13 to 15 per cent. In our studies there seems to be no appreciable difference in percentage of improvement between x-ray castration and surgical castration, although our series of surgical castrations is not sufficiently large to state this for a certainty. It would appear that castration in general has a temporary duration of improvement rather than a permanent one. It appears to retard the growth process materially for a duration, in cases which are improved, of about two years. It holds the cancer process in check but, in general, is not curative. The most striking effects in castration are those of male breast cancer, and here the work has been nothing less than spectacular. The change of the disease processes seems to be immediate in the cases of male castration, and the patients obtain the same striking improvement in general health as is shown in cases of carcinoma of the prostate which received castration.

75 East Seventy-First Street.

ABSTRACT OF DISCUSSION

DR. LAWRENCE A. POMEROY, Cleveland: My discussion of this paper will be based on the experience of Dr. E. P. McNamee and myself in the x-ray treatment of 73 patients with carcinoma of the breast. We follow the routine of the Tumor Clinic at Cleveland City Hospital in not treating the breast fields and axilla if the surgical removal has been adequate and if there is no microscopic evidence of involvement of the axillary lymph nodes. We have been surprised at the number of patients on whom a complete breast operation has been performed without any previous x-ray examination of the chest and of the bones most likely to be involved. Such an operation in the presence of metastasis is not justifiable and every effort should be made to exclude the presence of lung and bone metastases before operation. We have given ovarian irradiation irrespective of the age of the patient, the youngest being 33 and the oldest 83. We have done this because we have not known at what age to withhold the treatment and because ovarian irradiation adds only a few days to the usual postoperative x-ray series. We do not know whether to omit ovarian irradiation on patients who have ceased to menstruate or who have attained the age of 50 or 55 or of 60. We are not dermatologists. We are interested only indirectly in the dose that arrives on the skin. We are much interested in giving an accurate dose to the region of the ovaries. We have given at least 800 tissue roentgens to the region of the ovaries. The pelvic measurements (for x-ray therapy purposes) have varied from 15 to 24 cm. Taking the site of the ovaries as midway between the anterior and posterior pelvic walls, we have a depth dose of 57 per cent for the smallest pelvis and 38 per cent for the largest. The same x-ray dose to the skin delivers 50 per cent more to the ovaries in the small than in the large pelvis. This dose to the ovaries, expressed in tissue roentgens, should always be stated no matter what other factors of the x-ray dose are enumerated.

DR. J. SHELTON HORSLEY, Richmond, Va.: In the April 1944 issue of *Surgery* I reported a series of 25 cases in which bilateral oophorectomy with radical mammectomy was done for cancer in women in the premenopausal stage. These patients

have been traced. The last patient in this series was operated on Sept. 22, 1943; the first on Nov. 19, 1937. Two recurrences were reported. Since then there have been two other recurrences. As stated by Leo Loeb and others, mammary cancer after reaching a certain stage of development appears capable of growing under its own metabolism and is not dependent on estrogen. However, in the few cells sometimes left behind after a radical mammectomy and which may result in recurrence, it is probably necessary to have an estrogenic aid for them to grow. As emphasized by the authors, the relationship of the endocrines and their balance is not always constant There have been cases in which erection and copulation have occurred after removal of the testicles. Likewise after removal of the ovaries a biologic product from the other endocrines, as the adrenals, may possibly substitute for the estrogen of the ovaries. Such cases, however, must be quite rare, and it would seem that removal of the estrogenic stimulation for the few isolated cancer cells left after a radical mammectomy would render them inert and would greatly increase the chances of cure Probably many other surgeons have removed the ovaries in connection with a radical mammectomy, but I am unaware of any considerable number of cases in which this has been done and followed up for several years. Schinzinger of Germany had suggested this procedure in 1905 (Carcinoma of the Mammary Gland, *Munchen. med. Wchnschr.* **52**:1724, 1905), but according to the records he does not seem to have performed the operation. X-ray treatment of the ovaries undoubtedly is helpful, but according to Huggins it does not destroy the interstitial cells in the testis and he advises orchiectomy for cancer of the prostate; so it would seem difficult permanently to destroy the functions of the ovary by irradiation without in some instances damaging the surrounding tissues. Some of these patients have exaggerated menopausal symptoms which might be relieved by estrogen products, but such treatment would, of course, be absolutely contraindicated.

DR. W. E. CHAMBERLAIN, Philadelphia Patients with mammary cancer may and frequently do derive great benefit from having their ovaries irradiated. But who has definite answers to such questions as the following? "Is bilateral oophorectomy sometimes (or never, or always) superior to roentgen castration?" "Could it be that roentgen castration is better than oophorectomy because of some selective effect on the endocrines?" "Should roentgen castration (or oophorectomy) be used only in young women, or is there a possibility of benefit even in postmenopausal patients?" "When skeletal metastases from mammary cancer regress spectacularly after irradiation of the ovaries, why are the benefits so frequently short lived?" "Should the pituitary be irradiated in these cases? If so, when should that be done and what technical factors should be used?" Dr. Adair and his collaborators have contributed much toward the answers to such questions. A woman whose ovaries were removed at the age of 21 developed a particularly vicious and fast growing breast cancer at 48. Histologically it was undifferentiated in the highest degree. Axillary metastases were present when the breast tumor was first discovered. At radical mastectomy the gross findings, like the histopathology, pointed to early, rapid recurrence. But this woman had been receiving injections of estrogens (and latterly of diethylstilbestrol by mouth) for over twenty years. We discontinued this and now, more than a year later, she remains apparently well! Such a case enhances our interest in Dr. Horsley's proposal—routine prompt bilateral oophorectomy in premenopausal women with breast cancer In the choice between oophorectomy and irradiation, consideration must be given to the fact that in a certain percentage of young women even very large amounts of radiation may fail to put an end to ovarian function. Jacox has given quantitative data on this point. In at least a dozen instances in young women I have seen skeletal metastases from breast cancer regress following ovarian irradiation, recur or progress after an interval of from three months to a year, and then regress a second time after a second ovarian irradiation. Would these women have been better off with surgical castration? I have not been able to find the answer to that question either in my own records or in the reports of others

DR. NORMAN TREVES, New York: The use of estrogens to inhibit osseous metastases from mammary cancer is an unwarranted and dangerous procedure. It stimulates their growth. The use of androgens to check secondary bone deposits in breast carcinoma in women is an equally bad therapeutic measure. The patients do not do well on any type of endocrine therapy when malignant tumors of the breast have invaded bone. There is great difficulty in obtaining consent for castration in males; women consent to bilateral oophorectomy with less reluctance. The male feels that his sexual life is never over, while a woman approaching the climacteric usually realizes that there is a physiologic cessation of her reproductive functions. Consequently the number of male castrations is appreciably smaller. Dr. Adair did not have time to emphasize the finding that there were a number of cases in the present study in which the breast carcinoma had metastasized to the ovary. In the 6 cases in which the testes were examined after orchiectomy there was no evidence of metastases to the testes It has frequently happened that carcinoma of the breast metastatic to the ovary may bring about pathologic castration. An Italian was the only patient on whom Farrow and Adair had made a preliminary report. He refused castration until the metastases to bone caused him so much pain that he then consented to the procedure. It is now twenty-eight months since orchiectomy was performed. He had widespread metastases to the pelvis, lumbar spine, scapula and humerus, and these showed definite regression following castration. The second patient, an elderly man with associated cirrhosis of the liver, had a radical mastectomy and then was treated after a recurrence in the scalp was noted seven months after removal of the breast. Then he was treated with estrogen and there was wide dissemination of his mammary disease. He finally consented to orchiectomy. His death, three days after operation, was probably due to the associated cirrhosis of the liver and not to the effects of the operation. The third patient, an elderly man with recurrence, had definite relief from bone symptoms following orchiectomy and he has now remained well sixteen months after operation. The fourth patient, an elderly man with a localized tumor in the left breast and associated bilateral hydrocele, had an excision of the tumor. In repairing the hydrocele the procedure was simplified by performing a bilateral orchiectomy. It is now a year after this procedure and he has had no metastatic nodes in the axilla. It is possible that this tumor, 2 cm. in diameter, might have been taken care of by the local excision and we shall know only by the follow-up whether local excision with associated orchiectomy will control mammary cancer in the male. The fifth patient had pulmonary and osseous metastases. He was castrated in December 1943, yet he has had regression in the pulmonary metastases, and one area of bone metastases in the right ilium has not progressed since his operation. The youngest patient in this group, aged 39, failed to respond to castration. His disease progressed rapidly and he died four months after orchiectomy. Why castration for cancer of the breast in elderly males seems to be a much more satisfactory procedure than in young men cannot be explained at the present time and merits further studies.

Medical Institutions in Thailand.—The most important medical institution in Thailand was the medical department of the Chulalankarana University. The medical department, which had existed as a school since 1889, became a part of the aforementioned university in 1923, at which time a four year course was inaugurated. Two years of collegiate work were required before the candidate could begin the four year medical course. In 1929 the first class of 19 students was graduated. Both men and women were admitted, and 166 persons had been graduated with the degree of doctor of medicine by 1937. The medical department, at the time of the last report, had 44 instructors and professors and a library of 3,600 volumes.—Simmons, James S.: Global Epidemiology, Philadelphia, J. P. Lippincott Company, 1944.

THE INADEQUACY OF A STANDARDIZED DOSAGE OF PENICILLIN

IN THE TREATMENT OF GONOCOCCIC URETHRITIS

LIEUTENANT ROCCO G. LAPENTA
(MC), U.S.N.R.
ENSIGN ABRAHAM M. WECKSTEIN
H(S), U.S.N.R.
AND
LIEUTENANT COMMANDER HERBERT SARNOFF
(MC), U.S.N.R.
WITH THE TECHNICAL ASSISTANCE OF THOMAS C. KESSLER, PHM2c, U.S.N.R.

Reports of the efficacy of penicillin in the treatment of gonococcic urethritis have appeared. Previous studies [1] of clinical trials with this type of therapy have demonstrated its curative value. Later reports [2] on the rapidity of its therapeutic effect on gonococcic urethritis have further suggested that it approaches a 100 per cent clinical and bacteriologic cure. Reported failures with penicillin therapy are very rare.

The literature, to date, contains no report of a study which actually reveals the rapidity of bacteriologic cure based on serial cultures following each dose of penicillin. This study was set up to determine the exact point of bacteriologic cure within the limits of the units of penicillin used.

It has been our experience after culture study of several thousand cases of gonorrhea that clinical cure is not a definite indication of bacteriologic cure. Except in frank cases of gonococcic urethritis, smears are not a very reliable means of establishing diagnoses. Determination of bacteriologic cure necessarily varies with the ability to culture the gonococcus organism. It has been clearly demonstrated that cultures are far more reliable than smears as diagnostic aids and that some cultural methods are far superior to others.

For some time it had been noted that a good number of patients with gonococcic urethritis were being readmitted to our naval hospital and center dispensaries after having received 100,000 units of penicillin. Every one of these individuals had been previously discharged as clinically and bacteriologically cured. None of these cases were reinfections, since all of them had been under restriction for twenty-one days following penicillin therapy without possible reexposure. All had reported back within this twenty-one day period. Since this observation was at variance with another report [3] indicating that the total amount of penicillin required did not exceed 100,000 units and that all cases responded to penicillin and were cured from a clinical and bacteriologic standpoint within forty-eight hours, a preliminary attempt was made to test these observations. In 73 cases cultures were taken on a whole blood hemolyzed blood plasma agar medium.[4] In all of these cases 100,000 units of penicillin had been injected intramuscularly in doses of 20,000 units every three hours. A culture was taken in each case two days after therapy, seven days later and fifteen days later. Our experience in this preliminary study revealed that there were 13 (17.8 per cent) bacteriologic failures at varying periods of time following therapy. Accordingly, a carefully controlled series of cases were placed under study to verify these preliminary observations.

METHODS

One hundred and thirteen patients with gonococcic urethritis who were either sulfonamide sensitive or harbored sulfonamide resistant strains of the gonococcus were treated with penicillin in doses of 20,000 units given intramuscularly every three hours until each patient had received a complete dosage of 100,000 units. On being admitted to the ward and before penicillin therapy was initiated, a prostatic culture was taken on each patient to verify the diagnosis. Urethral cultures were taken in each case three hours following the initial dose and before each succeeding dose of 20,000 units. A prostatic culture was taken on each patient three hours following the injection of the fifth or final dose of penicillin. If the final prostatic culture was negative and the patient appeared to be clinically cured, the patient was discharged to duty. Each discharged patient received a slip permitting him only light duty for a period of ten days. In addition, each patient was recalled for prostatic cultures on three successive weeks but on varying days. Since each patient was under restriction

period of twenty-one days following the last dose of penicillin. All of these persons were treated in a single ward and were directly under our supervision.

Penicillin was also being administered for cases of gonococcic urethritis in several dispensaries in the Naval Center. Arrangements were made to take cultures of 106 cases following therapy of 100,000 units of penicillin administered in the same way but without serial cultures. Prostatic cultures were taken on each patient during the period of their twenty-one day restriction. Three negative cultures over a period of twenty-one days were required before these patients were considered bacteriologically cured. If the patient yielded a positive prostatic culture, he was returned to a dispensary for additional therapy. These positive cases

were then dropped from this study. This group of 106 cases was followed in order to check the findings on the experimental groups of 113 cases. All cultures were done under the supervision of one of us. The swab used in taking the cultures was fashioned from an applicator with one end tapered and bound with a small amount of tightly adherent absorbent cotton. The use of this type of swab is of paramount importance in taking cultures in a male patient. The penis was first thoroughly cleansed with tincture of green soap and water followed by 70 per cent alcohol. All prostatic and urethral cultures were taken by inserting a sterile swab for a distance of 2 centimeters into the anterior urethra and then rotated to collect the expressed fluid. The culture material was streaked on the whole blood hemolyzed human blood plasma agar medium, which has proved so very effective in growing the gonococcus. The swab was carefully rotated, so that all parts of its surface came in contact with the culture medium. All cultures were incubated in candle jars for forty hours and the colonies were then examined macroscopically and by the oxidase method. Smears and Gram stains were made of all oxidase positive colonies. No cases were considered positive unless the oxidase reaction was typical and typical staining and morphology were demonstrated microscopically.

In this study no attempt is made to determine the value of continued uninterrupted therapy with units of penicillin in excess of total doses of 100,000 units.

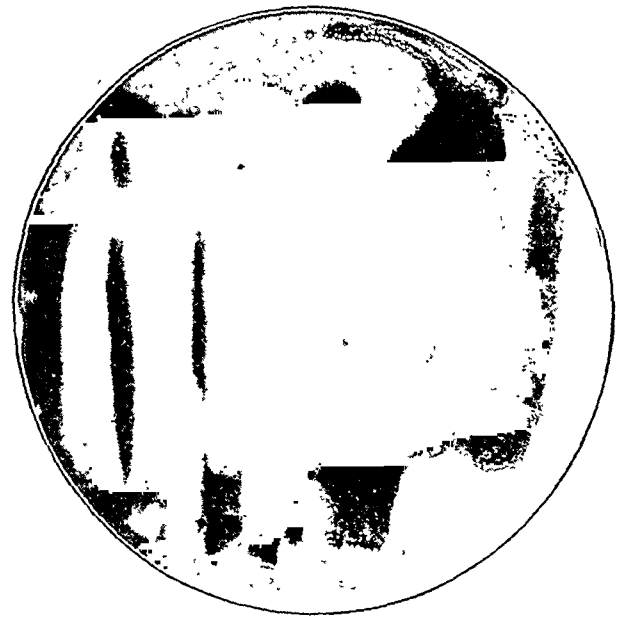

Fig. 1.—Culture plate of a typical case of gonococcic urethritis before penicillin therapy is instituted.

This investigation was set up to test the efficacy of the 100,000 units total dosage of penicillin which had been reported in previous studies.

OBSERVATIONS AND RESULTS

The results of the experimental study in the serial culturing of the 113 patients with gonococcic urethritis are shown in tables 1 and 3. These results reveal that, contrary to some reports of previous experimental studies, the dosage of 100,000 units of penicillin will not insure a 100 per cent bacteriologic cure. These figures reveal that only 70 per cent of the patients were bacteriologically cured with 100,000 units, 89 per cent with 200,000 units and 97 per cent with 300,000 units. One case required 460,000 units. No bacteriologic failures were observed after use of adequate doses of penicillin.

In the three month period during which this study was carried on, there was not a single readmission from this experimental group for gonococcic urethritis following the three negative cultures over a period of twenty-one days.

between the American republics to the end that there might be a steady and continuing improvement in health and welfare throughout the Western Hemisphere.

The resolution was not taken solely out of a spirit of pure humanitarianism. The constant aim of all the enlightened leaders of the nations of the Western Hemisphere is to achieve economic development and prosperity for the peoples of their respective countries. It was realized that, in order to bring about that effect, greater weight must be given to medicine and public health and close attention must be focused on them, not only, in the sense of controlling epidemic diseases, but also from the aspect of bringing about conditions appropriate to the development of healthy people able to cope with the economic problems of reconstruction —the bitter problems which will emerge to plague and harass all of us during the peaceful years when we are rebuilding in the ashes of this devastating war. It was recognized that there must be uniformity of procedures and practices throughout the hemisphere. It was foreseen that all the American republics must work together and apply in close collaboration and harmony tested health measures for the mutual benefit of all.

It must be emphasized that progress in health is international and hemispheric in scope. By its nature it cannot today be merely national. It follows that improvement of health services will be of distinct benefit to the United States of America and to all of the other American republics because it will be a factor in the economic development and prosperity of each country and thus, in turn, to the prosperity of the rest of the hemisphere.

The Institute of Inter-American Affairs has three divisions, namely the Health and Sanitation, Food Supply and Training divisions. The activities of the first two divisions are financed by appropriations from the United States and the governments of each of the eighteen republics now participating and through cooperative agreements with representatives of each government. The work is carried on through an intermediary organization composed of United States and national personnel and serving as an integral part of the national departments of health.

The training program is financed by the institute. Through the health and sanitation grants 165 students have completed their work and 145 are now in training. The total of 310 includes 172 trainees in public health, 73 in sanitary engineering and 65 in the medical sciences. These include a number of men who are returning to teach in the medical schools.

In a recent report from one of the trainees, the comment is made that the prestige of United States medical science is apt to be ascribed to the lack of material difficulties in accomplishment of work. Familiarity with North American hospitals discloses other factors responsible for the degree of success attained by medicine in this country, notably the fact that the American doctor is a tireless worker and is possessed of a high degree of scientific honesty and spirit of collaboration. This visitor sees medicine here as a series of teams that function with clocklike precision.

Such observations indicate that training programs not only are directly beneficial in promoting Latin American medicine and public health but also are believed to be providing one of the strongest links in the union of the Americas. Collaboration among medical men of the Americas is being furthered not only by the provision of fellowships but also in the actual execution of the cooperative health work in the southern countries.

The provision of medical and public health services for persons directly engaged in the war effort is an important function of the Cooperative Health Services. The control of malaria has received major emphasis. General activities include such features as physical examinations, vaccination, emergency medical care, the distribution of medicines and the provision and supervision of elementary sanitation. In this fashion an attempt has been made to improve the health and efficiency of the workers in rubber areas, on cinchona and sisal plantations, in the tin mines and in the rich, diversified mining regions of Brazil, as well as of highway and railroad workers in several of the countries. Sanitation and other public health measures have been intensified around air bases and in areas where our armed forces are stationed.

In addition to this work, which is largely of emergency and temporary character, the Cooperative Health Services are planned to supplement and extend existing activities and to introduce new patterns in the provision of a sound plan for immediate and long-term disease control. In accordance with the prescribed directives for the extension of public health, the campaign includes increased opportunity for the utilization of therapeutic and preventive measures through the construction, equipping and operation of hospitals, dispensaries, clinics and health centers; fundamental and widespread activities for improved water supply systems, for sewage disposal, insect abatement, and other sanitary measures; training of professional workers in their specialties and education of lay groups for the provision and practice of healthful living; and direction and evaluation of control measures through field and laboratory investigation.

The physicians of this hemisphere are sharing ideas and experience in the hospitals and health centers of Latin America and on the cooperative projects for the control of typhus fever in Colombia, El Salvador, Guatemala and Mexico, of schistosomiasis in Venezuela, and of diphtheria and typhoid in Uruguay. They are collaborating in the advancement of scientific knowledge through such studies as the use of penicillin in the treatment of yaws, experimental work in the treatment of filariasis, and investigations of onchocerciasis and tropical ulcer. Financial assistance has been given in support of the work of the Pan American Sanitary Bureau in numerous projects such as the provision of fellowships in military medicine for doctors from the medical corps of the other American republics, aid to the Inter-American Hospital Association, venereal disease control along the United States-Mexican border, medical and public health experts invited to attend conferences or visit institutions in the United States and the collection of biostatistical and epidemiologic information.

Latin American medicine is being strengthened by the building and equipping of facilities such as hospitals, clinics and dispensaries. A total of thirty-four hospitals has already been constructed or remodeled. Additional laboratories are also providing more adequate diagnostic facilities in many areas. Programs for establishment of nursing schools and training of nurses as well as short courses for hospital and visiting aides and laboratory technicians are providing essential subsidiary personnel. Consultants sent by the Institute of Inter-American Affairs have visited a number of the countries in connection with hospital planning, medical

school surveys and other phases of medical and public health work.

Medical science throughout the Americas is today profiting from a reciprocity that has been greatly accelerated in recent years. The advantages of this hemispheric teamwork are evident not only in the promotion of health, with its attendant benefits, but also in mutual understanding and respect.

The Inter-American Cooperative Health Program is demonstrating in a realistic manner that the nations of the Western Hemisphere can work together, that such cooperation is feasible and that it is profitable for all the peoples concerned.

The list of materials Latin America supplies North American industry is long. It includes copper, lead, zinc, tungsten, tin, mercury and other industrial metals. It includes sisal, henequen and abaca, balsa wood and mahogany, vegetable oils, nitrate, wool, hides and skins. It also includes the increasing production of rubber, quinine and rotenone producing plants. In return the other American republics buy great quantities of manufactured products from the United States. The purchase from this country of drugs alone has soared to hitherto unequaled figures during the war years.

Together with food supply and transportation, health is essential for the realization of the promise of the Americas.

A solid foundation has been laid by the work of many individuals and organizations throughout the hemisphere. Current activities provide a strong framework for the structure of international collaboration of the future.

INTRAVENOUS HISTAMINE IN THE TREATMENT OF MIGRAINE

PRELIMINARY OBSERVATIONS

STUYVESANT BUTLER, M.D.
AND
WILLIAM A. THOMAS, M.D.
CHICAGO

One of the theories regarding the mechanism of migraine comes from observations made by Sir Thomas Lewis in 1926.[1] He showed that there is a threefold reaction to local skin irritation: (1) local reaction at the site of the irritant, (2) local release of histamine at the site causing a wheal immediately around it and (3) a further release of free histamine into the circulating blood. It is well known that the intradermal injection of histamine in certain individuals will cause this second phenomenon of wheal formation, which is essentially a vasodilatation. It is generally believed that the phenomenon of migraine is precipitated by the release of histamine into the blood stream as the result of an allergic reaction and that the major attack of migraine develops only in those individuals whose tolerance to histamine is low and who would be hyperreactors at one phase of the syndrome to the intradermal injection of histamine. This is the third phenomenon described by Lewis as the response to local irritation.

2. Sheldon, C. H., and Horton, B. T.: Treatment of Meniere's Disease with Histamine Administered Intravenously, Proc. Staff Meet., Mayo Clin. 15:17 (Jan. 10) 1940. Horton, B. T.: The Use of Histamine in the Treatment of Certain Specific Types of Headaches, J. A. M. A. 116:377 (Feb. 1) 1941; The Use of Histamine in Meniere's Disease, Surg., Gynec. & Obst. 72:417 (Feb.) 1941.

Early in 1940 Horton and Sheldon[2] discussed the mechanism of Ménière's syndrome, believing it to be a local vasodilatation in the inner ear, and successfully treated a number of cases by subcutaneous and later intravenous histamine injections.

It should be clearly understood that these clinical phenomena are not due to allergy to histamine in the commonly accepted sense of the word but rather to a lowered tolerance of the organism to histamine present in the circulating blood as the result of an allergic stimulation. Histamine is present in all cells but in only minute quantities in the blood; it is only the individual with lowered tolerance to histamine who thus responds to its release into the circulation, whatever the mechanism of that release may be. The release of histamine into the circulation regardless of its cause is only momentary, since it is immediately taken up by the cells, where vasodilatation then occurs. Because of this very brief period when histamine is present in the circulating blood it seemed reasonable to us to assume that the tolerance of an individual would be raised more effectively by the long continued injection of histamine than by individual doses of increasing strength.

Our interest in the problem of the treatment of migraine with intravenous injections of histamine arose from two articles which appeared at almost the same time in 1943. Miles Atkinson[3] in May discussed the similarity of migraine and Ménière's syndrome, their relation to allergy and histamine production. In July Rainey[4] described a number of cases of Ménière's syndrome previously unsuccessfully treated by subcutaneous injection of histamine but which were greatly benefited by prolonged administration of intravenous histamine. With these two papers in mind it seemed to us that there might be therapeutic value in applying this technic to the treatment of migraine.

The criteria used to determine whether a headache was migraine or not are as follows:

The headaches are paroxysmal and unilateral, usually postorbital. They are frequently preceded by auras or prodromes which involve many of the cranial nerves, especially vision, hearing, taste, smell and various cutaneous sensations, as well as frequent disturbances of equilibrium. The history often shows a familial tendency and there is frequently evidence of allergy, especially to certain foods such as chocolate. The attacks usually involve nausea and vomiting, and characteristic of migraine is a freedom from any symptoms between attacks. Migraine equivalents frequently alternate with more typical attacks, especially in the case of paroxysmal tachycardia.

TREATMENT

We have used no patients in this series who could conceivably have headaches from any other cause such as sinusitis, neuralgia of the face or scalp, hypertension, skull injury, eye strain or brain tumor. Thirty-four patients with severe or moderately severe "pure" migraine remain who have been treated by the intravenous injection of 1 mg. of histamine as 2.75 mg. of histamine acid phosphate. This is diluted in 500 cc. of isotonic solution of sodium chloride and injected very slowly, the speed of injection usually starting at about

five drops per minute, the rate being increased as rapidly as is tolerated by the patient. Too rapid an injection will result in first a flushing of the face, often tachycardia and finally a typical severe headache which may be relieved by slowing the rate of injection or administration of epinephrine or ascorbic acid. The entire injection usually takes from four to eight hours. The blood pressure is taken hourly and any decided drop is considered an indication for cessation of treatment. Gastric analysis has been done in half our cases and has shown a high degree of secretion with very high acid values. The patients often complain of heartburn during histamine administration, but it is promptly relieved by mild alkaline powders. The onset of urticaria or asthma during the treatment is an indication for slowing the rate of injections or giving ascorbic acid. Patients have been given from three to four treatments with a day of rest after each one.

Certain precautions must necessarily be taken in the long continued use of a drug having such effects on the circulation and acid gastric secretion. No cases were used in which hypertension or cardiac or renal impairment was found to exist or in which there was evidence of mental or central nervous system disease. No patients with a history of peptic ulcer were given intravenous therapy, although 1 developed a duodenal ulcer twelve weeks after treatment.

Thirty-four patients with "pure migraine" were selected having an average age of 43 (table 1). The average age of onset of headaches was 18 and attacks had lasted from six to forty-eight years, an average of twenty-five. Not including 3 cases of status migrainicus the headaches lasted about nineteen hours and occurred twice a month.

No patients were used whose attacks were mild enough not to interfere with their regular life. The remaining ones were divided into moderately severe and very severe, the latter group (23) including only those who were incapacitated for more than eighteen hours or whose headache was so severe as to require opiates for relief.

We have found three different types of response as far as relief was concerned: (1) those whose relief was immediate, complete and apparently permanent, (2) those whose relief was immediate and complete but whose headaches recurred, usually in milder form, after weeks or months, and which were subsequently relieved by subcutaneous injections of histamine, (3) those who were not given immediate relief after the intravenous histamine but were relieved by one or more later subcutaneous injections and (4) those who obtained no relief.

TABLE 1.—*Summary of Cases*

Number of cases	34
Average age (32 to 63)	43 years
Age at onset (8 to 39)	18 years
Years symptoms present (6 to 48)	25 years
Duration of attacks *	19 hours
Frequency of attacks *	17 days

* Not including 3 cases of status migrainicus.

RESULTS

In a study of this group symptomatic relief from headaches as described by the patient was the only criterion which could be used; but this seemed of value in view of an average duration of twenty-five years of severe headache occurring every fortnight (table 2). Only 3 patients experienced no relief. Seven were improved either in severity of headaches or in decreased frequency or duration. Twenty-four were free from symptoms when last seen. All patients have been observed for at least six months since intravenous histamine therapy, 17 from twelve to eighteen months and 8 for more than eighteen months.

TABLE 2.—*Results*

Severity	Total Cases	Unimproved	Improved	Symptom Free
Moderately severe	11	2	2	7
Very severe	23	1	5	17
Totals	34	3	7	24

REPORT OF CASES

Four cases have been selected as characteristic: the first is one of great severity with complete relief most typical of our series; the second of very great severity having unusual features and with eventual relief; the third a case of moderate severity, complete relief, but with later development of a duodenal ulcer, and the last a case of great severity in which no relief was obtained.

CASE 1.—*Very severe headaches; complete relief from intravenous histamine.*

Mrs. H., aged 32, stated that the headaches began at 17, the menarche at 13. Her mother, father and twin sister had headaches. Three brothers had none. Since onset at 17 the headaches occurred only at menstrual periods until she was 23; on admission they occurred two or three times weekly, lasting from twelve hours to two days. They were unilateral and occipital, accompanied by photophobia, nausea and constant retching. During a headache her speech was indistinct. Morphine injections would often give no relief. She had had no headache during her two pregnancies. She was given three intravenous injections of histamine, having mild headache and heartburn during the first; for the latter she received 100 cc. of milk every half hour with relief. She has had no return of headache for fourteen months.

CASE 2.—*Very severe headaches; temporary relief from intravenous histamine; relief from further subcutaneous histamine.*

Mrs. P., aged 63, stated that the headaches began at 15, the menarche at 14. Her mother had headaches of such severity with "triple vision" that she committed suicide; one sister had headaches so severe that she developed melancholia. There were no living children. The headaches had been present for forty-eight years except during her two pregnancies. They are temporal and occipital, always unilateral. The headache was preceded by an aura of dimness of vision, when "everything was blurred and darkened but with spots of light like fireworks." The aura lasted thirty minutes and the headache began lasting one to six days; during this period she had double vision. The attacks occurred once to twice weekly and had been present so much of the time that she had been examined repeatedly for eye or brain disease. There was no relief from any medication, including morphine. Chocolate caused a skin rash and diarrhea. Examinations of the retinal and visual fields were normal. Four intravenous injections of histamine were given, the first preceded by 500 mg. of ascorbic acid intravenously in order to relieve the existing headache. One hour after beginning the second injection flushing of the face and neck occurred, relieved by intravenous ascorbic acid in the other arm. During each of the last two intravenous injections 500 mg. of ascorbic acid was added to the histamine salt solution. She was free from any

headache or visual disturbance for six weeks but then had two mild attacks two weeks apart, lasting about three hours each. She was then given subcutaneous injections of histamine weekly for six weeks without recurrence for seven months

CASE 3.—*Moderately severe headaches, relief, later a duodenal ulcer developed.*

G, a man age 40, married, stated that the headaches began at 17. His mother and his mother's mother had sick headaches. There were no siblings. The headaches occurred every three to fifteen days, averaging once a week They were temporal, occipital and always unilateral. They were associated with blindness, nausea and often vomiting He also had urticaria from eating eggs and would always get a headache from chocolate. The headache lasted typically about twelve hours. Gastric analysis with an Ewald meal revealed free acid 40, total acid 65. Three intravenous injections of histamine were given. The patient developed urticaria during the first two injections, which was relieved by slowing the rate of the first injection and by intravenous ascorbic acid (500 mg.) during the second. Three months later he developed a penetrating duodenal ulcer, which healed rapidly on medical management Gastric acid findings were unchanged during the second hospital admission He has had no headache for seventeen months

CASE 4.—*Very severe headache; no relief after four intravenous and many subcutaneous injections*

Mrs. H, aged 34, stated that the headaches began at 13, the menarche at 13. Her mother, two maternal aunts and two sisters had severe sick headaches For seven years the headaches occurred only at her menstrual periods, after 20 they increased in frequency, occurring every eight or nine days, lasting approximately thirty hours and causing her to go to bed During her two pregnancies at 26 and 30 years she was completely free during the second and third trimesters, and during lactation her headaches were infrequent and mild However, after the children had been weaned the attacks recurred with their same frequency and severity. Her only relief was from injections of ergotamine tartrate. Four intravenous doses of histamine followed by subcutaneous injections of increasing strength have failed to alleviate in any degree the pattern of the attack

SUMMARY AND CONCLUSIONS

1. Thirty-four patients with severe migraine were treated with intravenous histamine injections. Seven were improved and twenty-four became symptom free.

2. Intravenous histamine should not be given to patients with peptic ulcer or vascular disease and may be dangerous if indiscriminately used

3. Histamine is nonantigenic, and the body does not become sensitized in an allergic manner either spontaneously or by repeated injections, as may be the case in the higher protein aggregates which are capable of producing antibodies by injection or other routes of assimilation.

4. The observations recorded suggest a new method of attack on many problems which may be due to allergy.

Sectarian Medicine Unwanted.—Your timorous citizen with a backache may still choose to have his vertebrae adjusted; but if his boy is going to stop a bullet he wants him to have a good orthodox surgeon and plenty of penicillin There are sects and parties now only in those fields in which science has not yet been able to provide general principles, for example in psychiatry and medical sociology. The judgments of everyday doctors, of the health officers and of the military medical staffs are being accepted everywhere with astonishing confidence and no effective sectarian opposition.—Corner George W.: The Gifts of the Good Physician, University of Rochester, N. Y., 1944.

STREPTOMYCIN FOR TYPHOID

A PHARMACOLOGIC STUDY

HOBART A. REIMANN, M.D.
WILLIAM F. ELIAS, PH.D.
AND
ALISON H. PRICE, M.D.
PHILADELPHIA

In the search for antibiotic substances which are more bacteriostatic or bactericidal for gram negative bacilli than penicillin, Waksman and his associates isolated two apparently related substances, streptothricin [1] and streptomycin,[2] from the genus Streptomyces, which includes the soil actinomycetes. Of the two, streptomycin, obtained from a strain of Actinomyces griseus, is somewhat more active against certain pathogenic gram negative bacilli, including Eberthella typhosa, and is less toxic for the host.[3] It is also effective in controlling experimental infection in animals with a mixture of Proteus vulgaris and anaerobic streptococcus,[4] and with Pasteurella tularensis, Myocobacterium tuberculosis and Klebsiella pneumoniae.[4a] An opportunity to test the therapeutic effect of streptomycin on typhoid and to study its pharmacology in patients came during a local epidemic which began in December 1944. About 60 cases with eight deaths were reported, all arising from a carrier in a bakery. Because of the limited amounts of streptomycin available, only 5 patients with severe or moderately severe attacks were selected for treatment and study.

Streptomycin hydrochloride was supplied by Merck & Co., Inc., of Rahway, N. J. The potency of the first lots used varied from 110 to 130 units per milligram. A subsequent lot had a potency of 300 units per milligram and the last lot received was increased in potency to 430. The unit of potency is the amount necessary to inhibit the growth of a strain of Escherichia coli in 1 cc. of broth or agar.[5] The unit value seems out of proportion with the unit value of penicillin as measured against a standard strain of staphylococci, so that unitage as now expressed in millions may be readjusted later at a lower level or preferably established on the basis of milligrams of crystalline substance. An average daily dose of 100,000 units of penicillin with a potency

of 800 units per milligram weighs about 125 mg., but a daily dose of 4 million units of the best streptomycin of about 400 units per milligram used in this study weighed 10 Gm.

Sterile solutions for intramuscular injection were prepared in distilled water so that each cubic centimeter contained 50,000 units. Accordingly, 2.5 cc. (125,000 units) was injected intramuscularly in different areas at three hour intervals, making a total of 1 million units daily in patients 1 and 2. For patient 3 the amounts were doubled and then quadrupled. Injections of large amounts were painful and required the addition of 1 cc. of 1 per cent procaine hydrochloride solution. Patient 4 received streptomycin intravenously and patient 5 orally. Blood samples were obtained from each patient before treatment, every hour after the first dose for three hours, then every three to six hours for twenty-four hours, and thereafter every twelve to twenty-four hours, to measure the amounts of streptomycin present. Samples were taken from 2 patients every hour for three hours after the last dose and a few subsequent ones at three hourly intervals to determine the rate of disappearance from the blood. The amounts of streptomycin excreted in the urine were measured in daily twenty-four hour collections of urine. In patient 4 the units per gram of feces were measured, and in patient 5 the total output in the feces and its effect on the flora were studied.

The technic of measurement of streptomycin in the blood, urine and stool was based on the agar cylinder-plate diffusion method, using Bacillus subtilis, of Robinson and Smith.[6] Although B. subtilis was the test organism, the unitage in this study is expressed in E. coli units. A detailed report will be given elsewhere.[7]

REPORT OF CASES

CASE 1.—C. G., a man aged 31, noted malaise and chilly sensations beginning about Jan. 7, 1945. He remained at work for a week until the increasing severity of symptoms with severe chills, headache and fever confined him to bed. A remission of symptoms occurred about January 20, but fever, chills and drenching sweats recurred two days later. Slight deafness and sordes appeared. He was admitted to the hospital January 25 on the nineteenth day of the disease. The temperature was 105 F., the leukocytes numbered 6,700 and a blood culture contained five colonies of E. typhosa per cubic centimeter of blood, but typhoid bacilli were not cultivated from the stool until later. Sordes and rose spots were present. He was regarded as having a severe attack of typhoid. On the twenty-fifth day his temperature rose to higher level (chart 1) and he became more toxic, with mental confusion and somnolence.

Treatment with streptomycin began on the twenty-fourth day; 125,000 units was injected intramuscularly every three hours, a total of 1 million units a day. There was tenderness at the site of each injection about an hour or so afterward which persisted for several hours, but otherwise no untoward effects were noted. For a short period only 500,000 units was injected over a thirty-six hour period, but the original dosage was resumed during the rest of the ten day period, making a total of about 10 million units. The estimated amounts of streptomycin in the blood increased to about 5 units within six hours and maintained that level. The amounts rapidly diminished several hours after the last injection. From 13 to 56 per cent of the total daily doses was recovered daily from twenty-four hour collections of urine. Traces of streptomycin, estimated as between 2 and 3 units per cubic centimeter, were demonstrable in the spinal fluid on the ninth day of treatment.

Between thirty-six and forty-eight hours after treatment was begun the temperature began to decline steadily and reached normal on the thirty-seventh day. Symptoms and signs abated proportionately. Typhoid bacilli were present in the blood

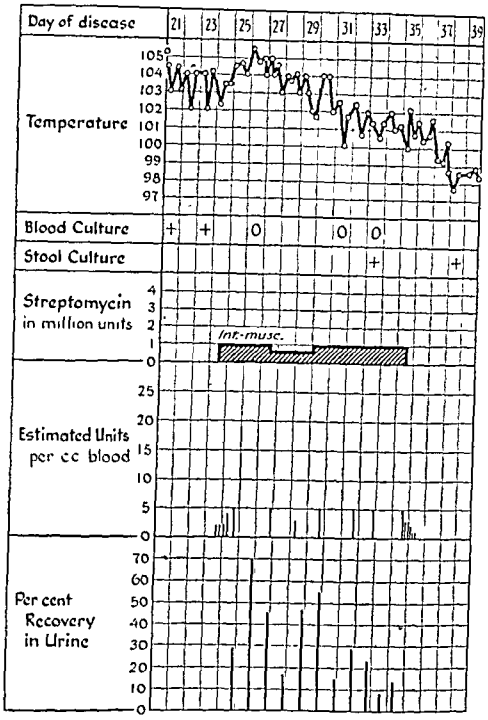

Chart 1 (case 1).—Intramuscular injection, 1 million units daily. Gradual decline of fever during therapy, with disappearance of bacteremia. Amounts of streptomycin in the blood are theoretically bactericidal.

before but not after treatment was begun. They were recovered from the stool on the thirty-third and thirty-eighth days, unchanged in their resistance to streptomycin.

Recovery in this patient may have been spontaneous or induced by streptomycin. At any rate the symptoms increased in severity before treatment, and recovery was synchronous with therapy.

CASE 2.—M. B., a waitress aged 49, went to bed about January 4 thinking she had a cold because of headache, fever and chills. A few days later diarrhea occurred with several bloody stools. There were rhinorrhea and epistaxis. The general condition became worse and she was admitted to Temple University Hospital as a patient of Dr. John Lansbury[8] on about the twenty-first day of the disease. She had a severe form of typhoid. The leukocytes numbered 4,700, and E. typhosa was present in the stool.

Streptomycin was injected intramuscularly beginning on the twenty-fourth day in doses of 125,000 units every three hours, or 1 million units daily, and continued for about nine days, a total of about 9 million units (chart 2). No clinical improvement occurred during therapy or for several weeks afterward. No evidence of toxicity from streptomycin was noted, but soreness was complained of for a few hours at the injected sites. The amount of streptomycin in the blood increased to 12 units per cubic centimeter within twelve hours after the first injection and remained at approximately that level during treatment. The blood cultures, sterile at first, became positive for E. typhosa during treatment despite the presence of 14 units of streptomycin per cubic centimeter of blood, or double the amount needed to kill the germ in the test tube. After

8. Drs. J. Lansbury and L. W. Whitney allowed us to study this patient and cooperated in her management.

treatment was stopped, streptomycin rapidly diminished and after nine hours could no longer be demonstrated in the blood. From 10 to 28 per cent of the daily dose was excreted in the urine. Streptomycin disappeared from the urine forty-eight hours after the last dose.

Treatment with streptomycin had no beneficial effect and bacteremia persisted probably because of insufficient dosage, although the amount present in the blood was more than enough to kill E. typhosa in broth, or because of some unknown factors which interfere with the action of the drug or protect the bacilli from its effects.

CASE 3.—R. H., a maid aged 24, ate food from the suspected bakery about January 5. A stool culture made during a survey revealed E. typhosa on January 24. The patient was well until January 27, when she noted severe headache, later chilliness which lasted twenty-four hours and malaise for three days, although she continued to work. On February 1 fever, malaise, constipation and nosebleed occurred. She was admitted to the Graduate Hospital of the University of Pennsylvania as a patient of Dr. H. L. Bockus [9] on February 2, the sixth day of the disease. Her temperature was 103 F., the pulse rate was 110 and the leukocytes numbered 4,500. Blood culture made on February 2 and four made thereafter were all sterile. E. typhosa was cultivated from the stool on occasions, as shown in chart 3. During the first four days of observation the patient was not toxic and the attack was regarded as moderately severe.

Streptomycin in larger doses was injected intramuscularly every three hours in 5 cc. (250,000 units) amounts, a total of 2 million units a day, as shown in chart 3. Because of the

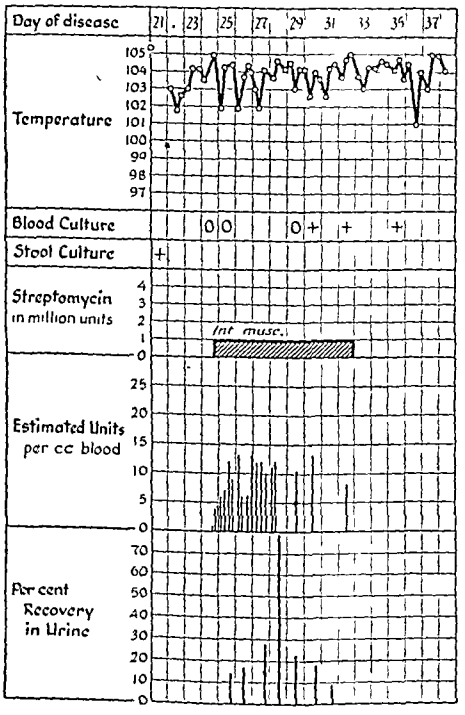

Chart 2 (case 2).—Intramuscular injection, 1 million units daily. No clinical effect from therapy; bacteremia present despite amounts of streptomycin in the blood more than the theoretical bactericidal level.

pain at the site of injection the amount was divided and injected into two places at once. Since no evident clinical improvement occurred, the dose after two days was doubled to 500,000 units every three hours, or 4 million units daily, and injected with 1 cc. of 1 per cent procaine hydrochloride solution. On the nineteenth day of the disease, or the seventh day of treatment, after about 24 million units had been given, the temperature dropped abruptly to normal and recovery ensued. Treatment was stopped one day later because of pain at the sites of injection after a total of about 30 million units had been given. Tender indurated masses at the sites of injection

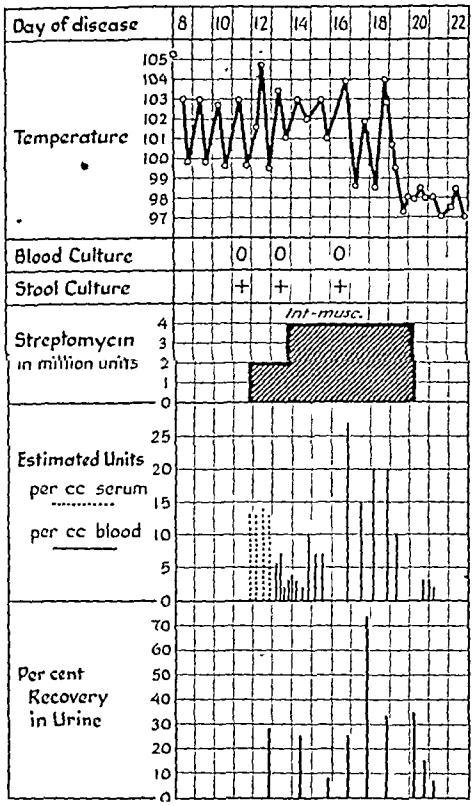

Chart 3 (case 3).—Intramuscular injection with 2 million, then 4 million units daily. Gradual decline of fever after start of therapy and crisis-like end with clinical recovery on the eighth day of treatment. E. typhosa persisted in the feces during treatment.

remained for several days, but no evidence of toxicity was noted. E. typhosa was cultivated from the stool during treatment.

Streptomycin was present in the blood one hour after the first injection. The first four measurements were made of serum in which the estimated amounts of streptomycin, 13 units, were about double those in the whole blood, as may have been expected. The estimated amounts in the blood during the first three days of therapy averaged about 7 units. After increased dosage larger amounts appeared, as high as 27 units. Amounts at levels higher than 12 units are subject to more accurate measurement.[7] After treatment was stopped streptomycin disappeared from the blood in eighteen hours. Streptomycin appeared in the urine in amounts similar to those in cases 1 and 2, averaging 25 per cent of the amount injected. None was detected in the urine forty-eight hours after the last injection.

Treatment with streptomycin seemed to precipitate a crisis-like termination in this case, although it took seven days to do it. Abrupt recovery is unusual in typhoid.

CASE 4.—M. M., a man aged 60, had typhoid fifty years ago. About Dec. 12, 1944 mild illness thought to have been grip began. The symptoms gradually became worse until severe chills and fever obliged bed rest. He was admitted to the hospital on Jan. 12, 1945 on about the twenty-first day of the disease with fever of 101 F., leukocytes 5,000. A blood culture was sterile. He did not appear to be very sick at first but soon did, with repeated shaking chills and fever of 104 F.

9. Drs. H. L. Bockus and E. Jobb allowed us to study this patient and cooperated in her management.

He was given empirically a total of 200,000 units of penicillin intramuscularly on January 15 and 16 and a course of sulfadiazine January 18, both without effect. On January 19 a massive intestinal hemorrhage occurred. The patient came under our care January 25. E. typhosa was isolated from the stool on this date and from several later ones. Blood cultures and the Widal test gave negative results. The patient's condition remained about the same until about the forty-fifth day, when toxicity became severe. There were restlessness and delusions alternating with somnolence. The stupor deepened by February 24, the sixty-fourth day of the disease, and his condition was critical. Intestinal bleeding recurred.

At this time streptomycin for intravenous use was made available. A daily dose of about 4 million units was injected by the continuous drip method. Streptomycin hydrochloride 1,350,000 units was dissolved in 1,000 cc. of isotonic solution of sodium chloride and allowed to run into a vein in eight

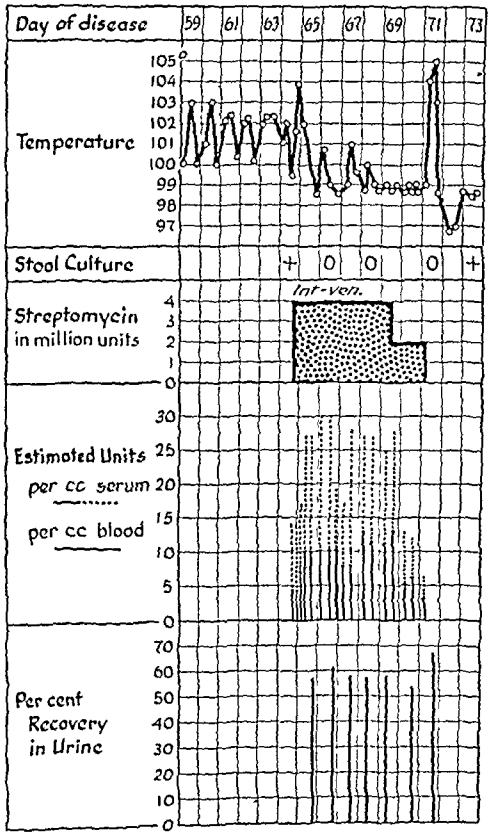

Chart 4 (case 4).—Intravenous injection with 4 million, then 2 million units daily. Abrupt drop of fever twenty-four hours after injection was begun and rapid recovery. Febrile reaction on the seventy-first day may have been caused by impurities in the drug. High levels of streptomycin in the blood and 130 units per gram of feces (not shown in the chart) were present. The feces were free of typhoid bacilli until four days after treatment, when only 40 units per gram was present.

hours, then replaced by similar second and third preparations during twenty-four hours. For every third thousand cubic centimeters 10 per cent glucose solution was substituted for the salt solution to reduce the danger of edema. A slight chill occurred about five hours after the injection was begun, but this had also occurred after many previous injections of blood or of fluid with salt, sugar or amino acids. As noted in chart 4, a few hours after the injection was begun the temperature rose as it had many times before, but twenty-four hours later it touched 98.6 F., coincident with a fall in pulse rate from 120 to 95 per minute. Striking clinical improvement occurred in the next thirty-six hours, the temperature declined and the patient became cooperative, oriented and alert. By the fifth day of treatment recovery seemed established and the daily dose was reduced to 2 million units to conserve the supply. A slight recrudescence occurred on the eighty-fourth day, lasting three days.

After seven days of treatment and apparent recovery the patient had a chill, followed by fever rising within a few hours to 105 F., restlessness and stupor. Intravenous therapy was stopped after about 23 million units had been injected. The temperature returned to normal after twelve hours, became subnormal and was accompanied with a shocklike state lasting about twelve hours, followed by recovery. Since there had been about fourteen similar but less severe episodes during the ten weeks of sickness it was impossible to decide whether the last one was a similar one or if it was a reaction to streptomycin. A sample of the streptomycin used when injected into 2 rabbits by the standard U. S. P. XII method caused fever in both, indicating the presence of a pyrogen.

With intravenous therapy the amount of streptomycin in the blood rose to an estimated 4.5 units one hour after the injection was begun and within twelve hours reached 10 units, a level maintained while the dosage was 4 million units. The amounts recorded in the serum were consistently higher, up to 30 units per cubic centimeter. After the dosage was reduced to 2 million units the amounts in the blood fell rapidly, as shown in chart 4. About 60 per cent of the daily dose was excreted in the urine.

Because of difficulty in collection the total daily stool was not weighed, but measurements on samples showed streptomycin in amounts of 105 units and 130 units per gram (0.1 to 0.13 unit per milligram) on the fourth and fifth days of treatment with 4 million units. The amount dropped to 80 units when the dosage was reduced and to 40 units two days after treatment was stopped. At this time typhoid bacilli reappeared in the feces, suggesting that too little streptomycin was present to suppress their growth and that some factors interfered with the action of the drug on the bacilli.

The recovery of this patient seemed to have been caused by streptomycin because of the large amounts of streptomycin in the blood, feces and urine and the apparent relationship of the decline of fever and symptoms with therapy. He became worse before treatment was begun and improved greatly in the next thirty-six hours.

Case 5.—P. F., a woman aged 21, noted chilly sensations, malaise and headache about January 4 but was not obliged to remain in bed until January 9. Remission occurred January '13, but the symptoms returned six days later and became severe. She was admitted to the hospital on the fifteenth day of the disease with fever of 106 F., rose spots, cough, deafness, bradycardia, mental confusion and diarrhea. The leukocytes numbered 7,000, and E. typhosa was present in the blood and feces. She was severely sick.

Streptomycin was not available for treatment until the fifty-seventh day of the disease. At this time there was temporary spontaneous improvement. The substance was given orally, 125,000 units every three hours or 1 million units a day for five days. The temperature, which had fallen somewhat before treatment, rose again and reached 102 F. during therapy with 1 million units. The dosage was doubled on the sixth day and doubled again to 4 million units on the seventh day, but no measurable streptomycin appeared in the blood, only traces (0.8 to 1.2 per cent) of the daily dose appeared in the urine and no clinical improvement occurred. During oral therapy almost all of the ingested streptomycin was excreted in the stools. On the fifth day of therapy 72 per cent was present (4 units per milligram) and on the sixth day 110 per cent, the latter probably due to accumulation from the previous day which was recovered by enema. With 4 million units given orally, the amounts in the stools increased to 10 and 19 units per milligram. At the same time, striking changes occurred in the flora of the feces as determined by Dr. G. H. Warren. In a specimen cultured before therapy, E. typhosa and E. coli were present in large numbers. After one day of oral therapy E. typhosa disappeared and E. coli was greatly lessened.

After several days of oral therapy E coli was almost completely eliminated and the stools lost much of their fecal odor.

The temperature continued to rise and oral therapy was replaced by intravenous injection in amounts of 2 million units for two days and 4 million units for four days, when the supply was exhausted.

Within a few hours after continuous intravenous injection streptomycin appeared in the blood and urine in amounts comparable to the preceding cases (chart 5), but the amounts in the feces diminished until only a trace, 145 units per gram, was present after four days. At this time typhoid bacilli reappeared, E. coli increased in numbers and on test the former were found to be just as sensitive to streptomycin as those isolated before treatment.

The result of therapy with streptomycin in this case is difficult to judge. Oral therapy was ineffective. The temperature, after intravenous injection was begun, rose even higher for a few days and then declined at a time when, unfortunately, no more drug was available. It rose again after treatment was interrupted, although the patient had no complaints. Several explanations may be offered: (*a*) The fever may represent the natural course of the relapse, (*b*) the temperature may have been increased from the sixty-fifth to the seventieth day by pyrogenic impurities in the drug and (*c*) it rose again on the seventy-second day because insufficient amounts of streptomycin were given or therapy was stopped too soon. Perhaps, as in other systemic infections, specific therapy to be effective must be given earlier in the disease, yet in case 4 a favorable effect seemed to follow treatment on the sixty-fourth day.

It is assumed that E. typhosa recovered from each patient was of the same strain, since all five were apparently infected from the same source. The bacillus obtained from both blood and feces of patients 1, 2 and 3 and from the feces of patients 4 and 5 was killed by 6 units, but not by 4 units when standard suspensions of 1,000 bacilli per cubic centimeter were incubated at 37 C. for forty-eight hours in the test tube. A laboratory stock strain of E. typhosa was found to be more sensitive to streptomycin; growth was inhibited by 1 unit.

Attempts were made to discover why in case 2 no clinical improvement occurred and E typhosa was still present in the blood, which contained 10 to 13 units of streptomycin per cubic centimeter, or twice the bactericidal amount necessary (6 units) in the test tube. The sensitivity to streptomycin of bacilli obtained before treatment began was compared with that of bacilli obtained from the blood after nine days of treatment, but both were killed by 6 units and not by 4 units. Exposure to streptomycin in the body, therefore, did not increase their resistance. A similar test of bacilli from patients 1, 4 and 5 gave the same result.

Further trial was made to see if 10 per cent normal human serum in broth interfered with the bacteriostatic effect of streptomycin as it does with penicillin,[10] but in this medium as little as 2 units but not 1 unit caused inhibition. If anything, serum enhanced the bacteriostatic effect. It is probable that other inhibitory factors are operative in the body.

Toxic Effects.—Except for a brief rise in fever a few hours after beginning intramuscular or intravenous injection in each case, which may have been caused by extraneous pyrogenic impurities, there were no other toxic effects of streptomycin. The severity of the disease may have masked mild toxic symptoms had they occurred. It is possible that the late reaction in case 4 was due to pyrogen. No exanthem developed, the erythrocytes, leukocytes and blood pressure changed no more than would be expected in typhoid, and no abnormalities appeared in the urine or feces. The urea clearance tests in each case after therapy and again two weeks later gave normal results.

Routes of Therapy.—Intramuscular injection in cases 1, 2 and 3 caused enough streptomycin to enter the blood and urine to inhibit, theoretically, the growth of E. typhosa in either fluid but failed to sterilize the blood in case 2. E. typhosa was present in the feces in all 3 cases during treatment. Traces of streptomycin estimated as between 2 and 3 units per cubic centimeter

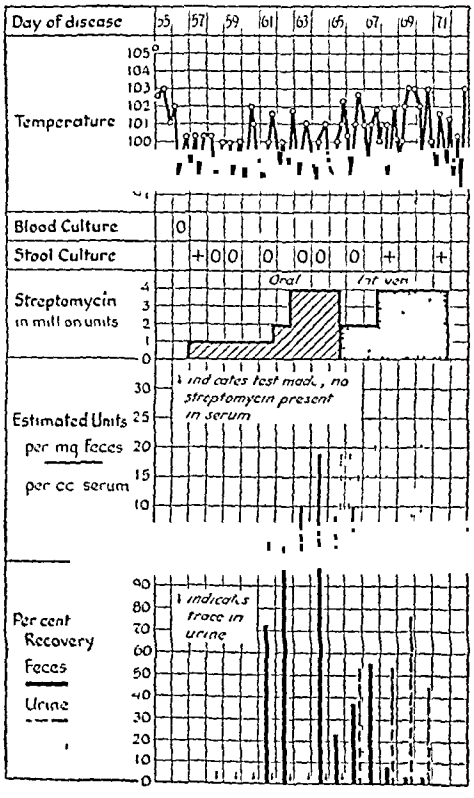

Chart 5 (case 5).—Oral therapy, 1 to 4 million units for nine days, then intravenous injection 2 million and 4 million units daily for six days. During oral therapy almost all streptomycin was excreted in the stool; only traces were present in the blood and urine. During intravenous injection the amounts rapidly increased in the blood and urine and disappeared from the stool after four days. Treatment was begun during a relapse on the fifty sixth day. It is possible that the temperature may have become normal on the seventy third day had more streptomycin been available

appeared in the spinal fluid of 1 patient given 1 million units daily.

Intravenous injection of large amounts in case 4, as expected, promptly caused large amounts in the blood and the excretion of 60 per cent of the daily dose in the urine. From 19 to 30 units per cubic centimeter of serum and from 400 to 1,000 units per cubic centimeter of urine were present. The amount in the blood was at times more than double the amount needed to kill typhoid bacilli in the test tube, and in the urine one hundred times more. These amounts are about the same as those obtained during intramuscular therapy in cases 2 and 3 and during intravenous injection in case 5. From 105 to 130 units per gram (0.1 to 0.13 unit per

10 Bigger, J. W.: Inactivation of Penicillin by Serum, Lancet 2: 400-412 (Sept. 23) 1944.

milligram) appeared in the feces. This quantity freed the feces of E. typhosa; but three days after therapy was stopped, while 40 units per gram (0.04 unit per milligram) of streptomycin was still present, the bacilli were again isolated. Apparently more than 40 units per gram of feces is necessary to inhibit growth.

Oral therapy in case 5 resulted in the excretion of almost all the streptomycin in the stool, the elimination of E. typhosa and a great reduction in the numbers of E. coli and of the odor of the feces. With doses of 1 million units, 4,000 units per gram (4 units per milligram) appeared in the feces, and with 4 million units, 19,000 units per gram (19 units per milligram). Soon after oral therapy was stopped the amounts fell rapidly and only traces were present in the feces four days later. Typhoid bacilli then reappeared and colon bacilli increased to their former numbers. The recovery of so large a percentage of the active substance proves the stability of streptomycin hydrochloride in the gastrointestinal tract. Traces appeared in the blood after oral doses of 1, 2 or 4 million units and only 0.8 to 1.2 per cent of the daily doses was excreted in the urine. In this respect the streptomycin compound used differs from certain preparations of penicillin, which when given orally may appear in adequate therapeutic strength in the blood and urine.[11]

The pharmacologic data suggest that, with the preparations of streptomycin now available, intramuscular or intravenous injection of from 1 to 4 million units daily is necessary to obtain minimal adequate bacteriostatic or bactericidal amounts (6 units per cubic centimeter) in the blood and urine for the treatment of systemic infection or urinary tract infection with E. typhosa. Oral administration of 1 million units daily apparently provided the minimal amount necessary to suppress the growth of E. typhosa and E. coli in the feces. It may be advisable in the treatment of typhoid and perhaps of other bacillary infections of the intestinal or urinary tract to give streptomycin both parenterally and orally, the latter during the disease and also in the convalescent period, to prevent reinfection and to prevent the carrier state. No data are available by which to prescribe the desirable length of time to prolong therapy after recovery. Oral administration of streptomycin may be useful as a prophylactic method under certain circumstances to prevent typhoid or other bacillary infections.

It is unsafe to judge the therapeutic value of streptomycin in the study of only 5 cases of typhoid, a disease of unpredictable severity and duration. But the presence of streptomycin in the blood, urine and feces in amounts more than enough to kill typhoid bacilli in the test tube, and the clinical improvement during therapy of 3 patients selected because of the severity of their attack, strongly suggest that the substance contributed to their recovery, if it did not actually cause it.

In case 1 gradual recovery coincided with the period of treatment and the drug may or may not have been curative. The failure of therapy in case 2, in which bacteremia persisted, cannot be explained except on the probable basis of inadequate dosage or by the presence in the body of substances inhibiting the effect of the drug. Streptomycin in the blood during bacteremia was in double the amount necessary to kill typhoid bacilli in broth culture. E. typhosa from the patients studied did not become resistant to streptomycin by exposure to it nor did serum protect the bacteria in test tube experiments. In cases 3 and 4 the abrupt end of the fever and recovery seemed to be brought about by the presence of large amounts of streptomycin in the blood. Spontaneous crisis-like recovery is unusual in typhoid. In case 5 treatment started orally on the fifty-seventh day at the beginning of a relapse had no clinical effect but cleared gram negative bacilli from the feces. Intravenous therapy caused large quantities of streptomycin to appear in the blood and was first accompanied by a rise of fever and then its fall toward normal. Its subsequent rise perhaps occurred because treatment could not be continued.

From the evidence at hand in 5 treated typhoid patients it can be said at present that streptomycin offers much promise as a substance capable of sterilizing the blood stream and urinary tract when injected in sufficient amounts parenterally, and of eliminating typhoid bacilli from the feces when given orally. Recovery of 3 patients during therapy suggests the therapeutic effectiveness of streptomycin for typhoid. In the present study streptomycin was not available until the epidemic was advanced and treatment was begun late in the disease. Perhaps earlier treatment in adequate parenteral and oral dosage would have provided better results.

Preparations of streptomycin are more stable than of penicillin, but in comparison with penicillin its umitage and bulk are far greater. When it is further purified or concentrated, streptomycin will probably not be any more toxic than penicillin. It is probable that substances are present in the body which inhibit to some extent the influence of streptomycin on E. typhosa.

SUMMARY

Streptomycin, a nontoxic antibiotic substance derived from Actinomyces griseus, when injected intravenously or intramuscularly in doses of from 1 million to 4 million units daily appears in the blood and urine in patients with typhoid in amounts theoretically sufficient to kill E. typhosa. Small quantities are excreted in the feces. When given orally, only traces appear in the blood and urine, and most of it is excreted unchanged in the feces in quantities excessive to suppress E. typhosa and E. coli. Both parenteral and oral therapy seem to be desirable in treating typhoid, the one to control systemic and urinary tract infection, the other to sterilize the feces, to prevent reinfection and to avoid the carrier state. There is evidence that different strains of E. typhosa vary in their resistance to streptomycin, but there is no evidence here of the development of increased resistance to streptomycin during exposure to it in the body.

Of 5 patients treated parenterally with streptomycin, recovery took place in 3 during treatment.

Sneezing.—Aristotle wrote that a sneeze was regarded as divine, and the Greeks of that age said "Zeus preserve you" to a sneezer. The corresponding Latin expression, according to Petronius Arbiter, was "Salve." The old Jewish formula is "Chayim Tobim" ("Good Life"), and the Moslem says "Sihhaten" ("twice health"). The modern "God bless you," "A vos souhaits," "Gesundheit," "Salud" and the like are relics of ancient superstition based on the idea that spirits are hovering everywhere.—Gordon, *Benjamin Lee: The Romance of Medicine*, Philadelphia, F. A. Davis Company, 1944.

PREGNANCY COMPLICATING DIABETES

PRISCILLA WHITE, M.D.
BOSTON

Recent published reports indicate that obstetric and diabetic clinics now agree that whereas the maternal mortality in diabetic pregnancies has been low fetal mortality has been high. The past fetal mortality rates have ranged from 30 to 60 per cent, depending on the length of pregnancy observed. If the study has been limited to the third trimester, the usual rate has been 30 per cent. If the entire period of pregnancy has been reported, it has been as high as 60 per cent.

The long period of observation of diabetic pregnancies by obstetricians and internists has revealed four salient abnormalities. These four abnormalities may be classified simply as first, maternal; second, obstetric; third, chemical, and fourth, fetal. My purpose in this discussion is to evaluate these abnormalities as they have occurred in a series of 181 consecutive diabetic pregnancies studied at our clinic between January 1936 and June 1944. In this series of cases there were one maternal and twenty-nine fetal deaths.

The prepregnancy abnormalities are two: vascular disease and hypo-ovarianism. Vascular disease is almost inevitable in young diabetic patients in whom the duration of diabetes exceeds fifteen years. Such patients comprise a large percentage of our own obstetric group and will soon comprise obstetric diabetic groups generally. It is now well established that arteriolar sclerosis as well as atherosclerosis occurs in diabetes. We find such involvement in the kidneys and eyes, as well as the better known lesions in the heart, aorta, the vessels of the extremities and the brain. Today nephritis has replaced sepsis and is replacing coma as a cause of death of young diabetic patients.

Ovarian failure is indicated by an increase in the serum level of follicle stimulating hormone, by amenorrheas and metrorrhagias. All of these are observed more and more frequently in young diabetic women. Atrophy of the ovary with poor follicular development is the only consistent pathologic change reported in the endocrine glands other than the changes observed in the pancreas itself. Thus, in spite of an outward appearance of youth and well-being, in obstetric diabetes we are dealing too often with a physically and gynecologically aged individual.

The abnormal obstetric course of pregnant diabetic patients is well known. The striking abnormalities are five: the easy, early spontaneous interruption of the pregnancy occurring in at least 25 per cent of the cases, the high incidence of preeclamptic toxemia occurring in 36 per cent, breech presentation in 33 per cent, uterine inertia common and failure of lactation in nearly 100 per cent. A normal obstetric course in patients with diabetes of long duration is almost conspicuous.

The chemical abnormalities which concern us here are (1) the low renal threshold for glucose, (2) water retention and (3) the imbalance of the sex hormones of pregnancy. The low renal threshold for glucose, which is physiologic for pregnancy, complicates the disease diabetes. The loss of glucose in the urine may exceed 100 Gm. per day, even with nearly normal levels of blood sugar. If uncorrected, this predisposes the patient to acidosis and, if overcorrected, to insulin hypoglycemia. Profound disturbance of water balance characterizes pregnancy in diabetic patients. This is shown clinically by the great gain in weight, visible maternal edema, hydramnios and fetal edema. An imbalance of the sex hormones of pregnancy, fall of pregnandiol and rise of chorionic gonadotropin has occurred in 70 per cent of the 181 cases under discussion here.

Fetal abnormalities are physical, chemical and pathologic. A birth weight above the average for the period of gestation has been found in 80 per cent of the infants of diabetic mothers. The size of the infant appears to be due to three distinct factors: obesity, edema and splanchnomegaly, the liver, spleen and heart being especially involved. The second physical abnormality is the high incidence of congenital defects usually involving tissue which is mesenchymatous in origin.

On the first postnatal day respiratory, sugar and temperature regulatory difficulties may be encountered, and forty-eight hours after delivery the universal occurrence of jaundice.

The pathologic characteristics of the infants of diabetic mothers are almost diagnostic of maternal diabetes. They are enlargement of the liver, spleen and heart, excessive hemopoiesis of the liver and spleen and islet hyperplasia.

All of these four abnormalities, maternal, obstetric, chemical and fetal, contribute to the complications of obstetric diabetes. Some of them we can exclude as not being of prime importance and others we can include as being of prime importance. Thus the diabetic emergencies coma and hypoglycemia have played no role in the unfavorable fetal outcome in this series of patients, and congenital anomalies contributed to a fetal death *but once*. *In this series imbalance of the sex hormones* of pregnancy appears to be the most important single harmful factor. In this series it is related to premature delivery, toxemia, disturbance of water balance and the abnormal fetus. Thus, when the hormonal balance was normal, as it was in 52 of our 181 cases, the incidence of premature deliveries was zero, the incidence of toxemia of pregnancy 2 per cent, and the *fetal survival* approached that of nondiabetic pregnancies, 96 per cent. In contrast to this experience, in 38 cases in which an abnormal hormonal balance was observed premature delivery occurred in 40 per cent, preeclamptic toxemia occurred in 50 per cent and the fetal survival was 50 per cent. Since the imbalance of the sex hormones of pregnancy occurred in abnormal clinical cases with poor fetal survival and the production of a characteristic fetus, an attempt was made in 91 cases to correct the imbalance, to see if premature deliveries could be prevented, toxemias altered or averted, fetal survival raised and a normal fetus produced. In the group so treated the incidence of premature delivery fell to 15 per cent, preeclamptic toxemia appeared to be altered and prevented and fetal survival rose to 90 per cent. It is difficult to measure the effect of hormonal correction on the incidence of toxemia in this series of cases, for the early ones were treated only after symptoms of toxemia had developed. In the past few years the therapy has been inaugurated on chemical evidence only and the incidence of toxemia in the latter group has fallen to 5 per cent.

From this study the rules for the management of the pregnant diabetic patient in our clinic have been evolved. Obviously not all of our cases have been treated in the same fashion. This management is

From the George F. Baker Clinic of the New England Deaconess Hospital, Elliott P. Joslin, medical director.
Read before the Section on Obstetrics and Gynecology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

diabetic, obstetric, endocrine and pediatric. The diabetic diet should be liberal in calories, 30 per kilogram of actual body weight, high in protein, 2 Gm. per kilogram of body weight, and adequate in carbohydrate, up to 200 Gm. daily, 150 for the mother and 50 for the fetus. Because of the low renal threshold multiple small doses rather than a single large dose of insulin have been employed. Sodium chloride intake is restricted and in abnormal cases ammonium chloride is administered.

The delivery in the abnormal cases is premature, the time of choice being the latter part of the thirty-seventh or the early part of the thirty-eighth week. Cesarean section for this particular group is my personal choice. The anesthesia is spinal and sedation is prohibited.

Various forms of endocrine therapy and various routes of administration have been used in this series of 181 cases. The best and most economical to date is diethylstilbestrol intramuscularly and progesterone intramuscularly. The average daily dose of each is 15 mg. The infant requires more than average drainage, mechanical stimulation, dehydration, heat and oxygen.

COMMENT

The reason for the abnormal clinical course of diabetic pregnancies may be sought in the abnormal physical, endocrine and chemical background of the diabetic woman. It does not seem illogical to argue that these make her liable to a disturbance of the sex hormones of pregnancy, which imbalance accounts for the high incidence of early, spontaneous, interrupted pregnancies, preeclamptic toxemia, uterine inertia and failure of lactation. Not only does this hormonal disturbance alter the course of pregnancy, but it may be responsible for the production of the abnormal fetus, contributing to fetal edema, splanchnomegaly and excessive hemopoiesis. The fetal survival and the clinical course have undergone a profound change with substitutional estrogen and progesterone therapy. Spontaneous correction of the imbalance can occur. Many women without diabetes can probably compensate and correct such an imbalance. The diabetic patient with a suboptimal hormonal production and metabolism can rarely correct this imbalance spontaneously.

CONCLUSION

Maternal survival in a series of 181 consecutive diabetic pregnancies was 99.5 per cent. Fetal survival for the total series was 84 per cent, but it varied with the occurrence of normal or abnormal balance of the sex hormones of pregnancy. If the sex hormones of pregnancy were abnormal and uncorrected, fetal survival was 50 per cent; if they were abnormal but corrected, 90 per cent; and if they were normal, 96 per cent.

81 Bay State Road.

ABSTRACT OF DISCUSSION

Dr. Henry Dolger, New York: I am not an obstetrician, but anybody who has treated diabetes has been appalled by the fetal mortality among diabetic patients. At the Mount Sinai Hospital the results in the clinic in the past four years have been most unsatisfactory, with not a single fetal survival. None of the patients received endocrine therapy and despite careful control of the diabetes they all went on to ultimate eclampsia or to spontaneous delivery of a macerated fetus. Dr. White's paper is important for two reasons: First, it is a remarkably large series to be produced by one group (I believe that Dr. White and the obstetrician and pediatrician attended each one of the patients). Second, so many of these patients have been delivered spontaneously. There are some who feel that most diabetic patients will deliver spontaneously with little or no attention to the diabetes. In Chicago some claim they can deliver a living baby to any diabetic patient just by cesarean section in the thirtieth week, which is quite radical. On the other hand Miller, Hurwitz and Kuder published a most pessimistic article regarding pregnancy in diabetes. They stated that the fetal and neonatal mortality among diabetic patients was four to five times that among nondiabetic women and that this increased fetal and neonatal mortality was evident even twenty years before the onset of the diabetes. This could not be corroborated by analysis of our clinic material. We found that before patients developed the clinical picture of diabetes they did not have any increased fetal or neonatal mortality, and this, I believe, agrees with Dr. White's data indicating that women are normal in their childbearing capacity until they develop diabetes. The concept of hormonal imbalance is not yet generally accepted as the etiologic factor in abnormal diabetic pregnancy. Nevertheless Dr. White's successful results speak for themselves and have not been duplicated anywhere. It may be that there is more to this than just endocrine therapy—I believe that an important factor is the close cooperation of internist, obstetrician and pediatrician, which exists so uniquely in Dr. White's clinic.

Dr. William J. Dieckmann, Chicago: I am familiar with the work from Dr. White's and Dr. Joslin's clinic, and I have no question as to their treatment of diabetes. I do question the termination of pregnancy early. My associates and I have not been practicing it, and while our fetal mortality is rather high in diabetes, it is not as high as 50 per cent, as I recall Dr. White gave in the untreated cases. We have not used any endocrine therapy for our patients. When Dr. White some years ago, working with the Smiths, first suggested the use of endocrine therapy, I believe I asked her if it was not the excellent antepartum care which she and the obstetricians in charge were giving these patients rather than the endocrine therapy. I believe she will answer in the negative, but I hope in closing that she will elaborate on this point. I believe the only other clinic in the country that feels as she and her group do with regard to premature termination of pregnancy is Dr. Wilder of the Mayo group. If we find severe toxemia developing in the diabetic patient we do terminate prematurely, but in the well treated diabetic patient who presents no evidence of toxemia we do not terminate before term, and then we prefer the patient to go into labor of her own accord.

Dr. R. Carrasco-Formiguera, Puebla, Mexico: There is only one point I wish to stress, about people being or not being normal and the correction of diabetes before pregnancy. It has been my experience (and I shall be glad to know what Dr. White's experience and opinions are in these people) that the fact has been observed of abnormally big babies having been born to a great number of diabetic patients. That was noticed so far back as twenty or more years before diabetes was discovered. This happens in such a large proportion of the cases that it cannot be devoid of significance. I am almost sure that this significance has something to do with the relation between the diabetes and the endocrine balance.

Dr. Priscilla White, Boston: As far as the good results or relatively good results in our clinic being due to the patients' antepartum diabetic care, I do not really think that is the answer because at regular intervals, for financial reasons, I am forced into a control period when the patients will receive exactly the same medical and obstetric care without endocrine treatment, and our statistics fall back to the lower levels we observed prior to 1938. Whatever produces diabetes is probably a long, slowly acting mechanism, so that it is logical to believe that some diabetic women will have abnormal pregnancies prior to diabetes probably for much the same reason that exists after the onset of diabetes. I cannot make a comparison of such statistics in our own series of patients because our obstetric practice is largely derived from our former juvenile diabetic patients, and so the first pregnancy is usually a diabetic pregnancy.

Clinical Notes, Suggestions and New Instruments

SEVERE ASTHMA: DELAYED SENSITIZATION TO PENICILLIN

DAVID E. PRICE, M.D.; DONALD J. MCNAIRY, M.D., AND EARL L. WHITE, M.D.
P. A. Surgeon, P. A. (R) Surgeon and Surgeon, Respectively, U. S. Public Health Service
NORFOLK, VA.

Penicillin has been widely acclaimed for its lack of unpleasant or dangerous side effects, so that occasional reactions probably due to it may be overlooked as coincidental. Several references to allergic manifestations accompanying or following the administration of penicillin call attention to the occasional simulation of serum sickness.[1] From the published accounts it appears that not one of these reactions has been alarming. It is our purpose in reporting the following case to describe an allergic reaction of unusual severity:

G. L. S., a white man aged 24, was admitted to the Hampton Roads Medical Center, Norfolk, Va., on July 28, 1944 for the treatment of primary syphilis. Aside from the penile ulcer and inguinal adenitis, the complete physical examination was normal. Family and past histories revealed that neither he nor any close relatives had suffered from allergic disease, even in mild form. On admission, dark field examination of the lesion disclosed Treponema pallidum, and the Kahn standard precipitation test for syphilis was positive (80 Kahn units). The hemoglobin and the white blood cell count were normal, and no eosinophils were reported in the differential count. The urine was cloudy and contained a trace of albumin, 45 pus cells and 1 red blood cell per high power field but no casts. The cerebrospinal fluid was normal.

The patient was treated for eight days with penicillin dissolved in 5 per cent dextrose in distilled water. The total dose was 2,400,000 units divided into sixty doses of 40,000 units administered intramuscularly at intervals of three hours. Two batches of penicillin were used, each the product of a different manufacturer, and the solvent was a solution commercially prepared for parenteral use. At the end of treatment the penile ulcer was epithelized, the urine normal and the serologic test for syphilis positive (20 Kahn units). The patient had experienced no unpleasant symptoms during the treatment and was discharged from the hospital on Aug. 7, 1944 clinically and symptomatically improved.

Forty-eight hours later, on August 9, he was readmitted because of asthma, giant urticaria, fever and malaise which had begun that morning. He was very uncomfortable, complaining chiefly of the intense pruritus. There were large wheals scattered over the entire body, including the palms and soles, so that he could not make a fist and walking was painful. Auscultation revealed generalized wheezing rales throughout both phases of respiration. The heart sounds were not clearly heard because of the asthma but did not seem abnormal. The temperature was 102 F., pulse rate 110 and respiratory rate 20.

Epinephrine in oil 1 cc. intramuscularly twice daily on August 9 and August 10 produced a gratifying subsidence of symptoms except for a very mild exacerbation each evening. There was a remarkable association between the height of the fever and the intensity of urticaria and asthma. On the evening of August 11 the symptoms were worse and the temperature was rising. Reexamination at that time disclosed patches of urticaria, a reddened tongue and injected pharynx, but no abnormality of the tonsils, the chest full of musical rales, generalized adenopathy and tenderness of the entire upper abdomen. The spleen was not identified. Following additional epinephrine and sedation the patient spent a comfortable night and throughout the next day appeared to be improving rapidly and desired to return home.

Suddenly, shortly before 8 p. m. on August 12 he had a seizure of coughing and when examined a few minutes later was found to have breath sounds obscured by wheezing rales. The temperature was 103 F. and the pulse rate 104. He rapidly became weak, the pulse rate rose to 150 and the blood pressure could not be measured. He became comatose and mildly cyanotic and the rectal temperature rose to 105 F. He was not expected to survive the attack but responded dramatically to 1 cc. of aqueous epinephrine followed by 50 cc. of 50 per cent dextrose intravenously. Oxygen was not used because it was not available at that time. By 10 p. m. he was fully responsive, the temperature had begun to decline and the blood pressure was 140/80. His only complaint was weakness and intense thirst. He slept well the remainder of the night, and in the morning the temperature and pulse were normal and there was only an occasional rale on deep inspiration. The heart sounds were normal. The patient felt well and from then until discharge on August 15 he had no further allergic symptoms but was given phenobarbital ½ grain (0.032 Gm.) and ephedrine sulfate ⅜ grain (0.024 Gm.) prophylactically. Laboratory work was not available during the worst of the attack, but several hours after it the only unusual feature was an eosinophilia of 8 per cent.

On August 14 a scratch test was performed. Neither of the two lots of penicillin with which the patient was treated was still available for use in skin testing, but the product of a third pharmaceutical company, in a concentration of 20,000 units per cubic centimeter, gave a negative result.

One cannot infer from this experience that the sensitizing agent was the active principle of the commercial penicillin. It does suggest that there are substances in commercial penicillin which are capable of producing sensitization leading to allergic manifestations of alarming intensity. We were impressed by the delay in development of sensitivity and the remarkable resemblance of the clinical picture to that of serum sickness. As pointed out by Feinberg,[2] refinements in manufacture will allow the production of the active therapeutic agent freer from foreign substances, so that sensitization may be still more unusual in the future.

DELIVERY OF QUADRUPLETS BY CESAREAN SECTION UNDER CONTINUOUS SPINAL ANESTHESIA

JOHN C. ULLERY, M.D., PHILADELPHIA

The incidence of quadruplets varies in different countries. Guzzoni in 1889 published an analysis of 50,000,000 births in which quadruplets occurred once in 757,000 births. In 1895 Hellin, whose work was based on South German statistics, suggested the following easily remembered ratios: twins once in 80 births, triplets once in 80 × 80 (6,400 births and quadruplets once in 80 × 80 × 80 (512,000) births. Greulich [1] published in 1930 a study of more than 120,000,000 births reported from twenty-one countries between 1915 and 1925. He found that quadruplets occurred once in 670,734 (87.5 [2]) births. According to these statistics about five sets a year should be born in the United States. The report here is of quadruplets born on Nov. 1, 1944 by cesarean section. A survey of the literature fails to reveal any previous quadruplets in which cesarean section was performed.

The history of the mother is important, as it reveals the indication for the cesarean operation. Mrs. K. C., white, aged 31, was delivered by cesarean section two years before, following a severe, rapid abruptio placentae. She had a normal antepartum course in this, her first, pregnancy. On Sept. 8, 1942, when only two weeks from term, she developed severe pain

From the Lying-In Unit of the Pennsylvania Hospital.

1. Greulich, W. W.: The Incidence of Human Multiple Births, Am. Naturalist **64**: 142 (Jan.-Feb.) 1930.

in the abdomen. Despite immediate cesarean section the baby was stillborn, and the placenta separated with a large retroplacental clot and much infiltration of blood throughout the uterus, both tubes and ovaries, and extending out to the lateral pelvic walls. The uterus contracted well and was closed without complications.

Her postpartum period was quite stormy and her temperature remained elevated from 104 to 106 F. for twelve days. She eventually recovered and was discharged four weeks after operation.

In this pregnancy the last menstrual period was March 12, 1944, with the expected date of confinement Dec. 19, 1944. During the first four months of the antepartum period there was considerable nausea and vomiting and it was necessary to hospitalize the patient for a week in June for pernicious nausea. She responded well and was discharged improved

In August the uterus was found to be larger than normal for the duration of pregnancy, the fundus extending three

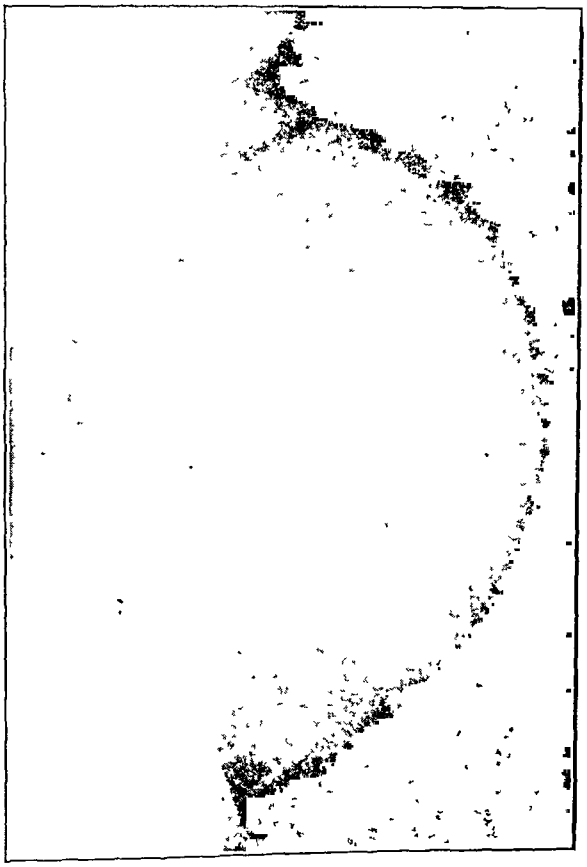

Fig. 1.—Appearance of four fetuses

fingerbreadths above the umbilicus, and x-ray examination revealed the presence of four fetuses (fig. 1). She was immediately hospitalized and remained there until three weeks after her delivery. During this time her uterus enlarged rapidly, until near the termination it was difficult for her to turn from side to side. She was given a high vitamin diet and progesterone 5 mg. every other day, plus iron and extra vitamins.

On October 24 she began to have some irregular uterine contractions and the uterus became quite tense. This continued for several days, and repeated x-ray examinations gave the estimated weight of the babies as approximately 3 pounds (1.3 Kg.) each. Because of the previous cesarean section and the stormy convalescence, it was felt that possible rupture of the uterus might be imminent and that any labor might precipitate this condition. Another cesarean section offered the safest procedure to avert it.

The choice of anesthesia was considered important, and continuous, fractional, spinal was chosen for its low toxicity and safety and as it does not cause narcosis or anoxemia to the baby. This was especially important, as one of the great causes of death of premature infants at birth is anoxemia from narcotizing anesthetics.

Accordingly, on November 1 an initial dose of 40 mg. of procaine hydrochloride was injected into the second lumbar interspace in 2 cc. of spinal fluid. The anesthetic was prompt and of the rapidly ascending type, reaching the clavicles in a period of five minutes. The maternal blood pressure dropped from 120/80 to 80/60 (fig. 2). At this moment 4 cc. of spinal fluid was withdrawn through the continuous spinal apparatus. Fifty mg. of ephedrine sulfate was administered intravenously along with a simultaneous clysis of glucose in isotonic solution of sodium chloride. The pressure promptly returned to 110/70 in eight minutes. A classic cesarean section was then performed. One placenta was on the anterior wall, and it was necessary to go through it to reach the babies. The first baby was delivered as a bilateral footling, the second also as a double footling, and the third as a vertex. These were all female babies and were enclosed in a single sac. The fourth infant was a male and was in a separate amnion with a small separate placenta (fig. 3). It was delivered as a double footling. The intravenous administration of 1 cc. of pitocin in 5 cc. of isotonic solution of sodium chloride allowed the uterus to contract well and the placentas were removed, with a measured blood loss of 300 cc. A routine closure of the uterus in three layers with continuous sutures then followed. The abdominal wall was also closed with continuous sutures in the peritoneum and fascia, and the skin was closed with clips. The maternal blood pressure remained at 120/80 throughout the operation.

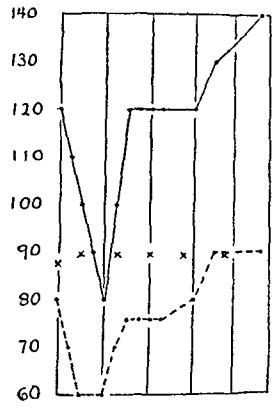

Fig. 2.—Systolic blood pressure (solid line), diastolic (broken line) and pulse (X's) Fifteen minute spaces

The birth weights of the babies were 3 pounds 14 ounces (1,758 Gm.), 3 pounds 9 ounces (1,616 Gm.), 3 pounds 1 ounce

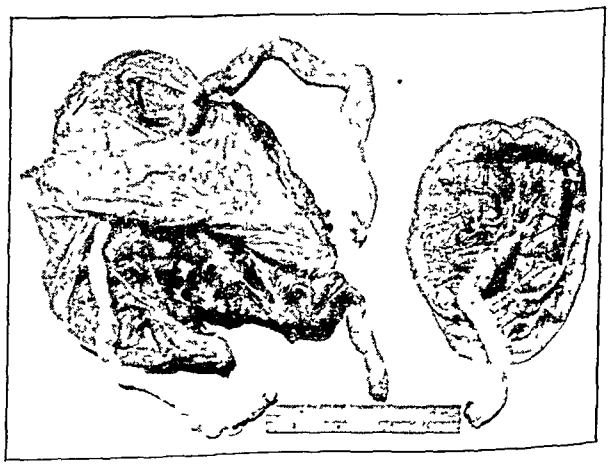

Fig. 3.—Separate amnion and placenta of male fetus and amnion and placenta of three female fetuses.

(1,389 Gm.) and 2 pounds 14 ounces (1,304 Gm.). They all breathed and cried instantly on removal from the uterus and showed good muscle vigor. They were placed in separate incubators at once and kept there for one month. Gradually the oxygen was turned off and the incubators were opened and then the babies were placed in premature hot beds. At the end of six weeks their respective weights are 4 pounds 15 ounces (2,240 Gm.), 4 pounds 14 ounces (2,211 Gm.),

4 pounds 6 ounces (1,984 Gm.) and 4 pounds (1,814 Gm.). Their feedings have consisted of breast milk from a milk bank stationed in the hospital.

COMMENT

The birth of quadruplets is reported here because of the unusual type of delivery and for the interest attached to the anesthetic employed. The safety factor of the continuous spinal anesthesia is emphasized, as shown by the prompt withdrawal of 4 cc. of spinal fluid containing some of the procaine, and the return of the maternal blood pressure to normal. In addition, the lack of narcosis or anoxemia was a vital factor in the healthy condition of the babies at birth and enabled them to breathe and cry at once without resuscitation Likewise the anesthetic contributed in a large measure to the rapid convalescence of the mother. She was able to eat a soft diet of food a few hours after delivery and showed no nausea or postoperative abdominal distention.

Special Articles

The following article is republished from the Epidemiological Information Bulletin *of the Health Division of the United Nations Relief and Rehabilitation Administration. It represents the best present opinion on the outlook for the development of epidemics in Europe.*—EDITOR.

THE EPIDEMIC OUTLOOK IN EUROPE

KNUD STOWMAN
Chief, Epidemiological Information Service
WASHINGTON, D. C

The war in Europe is apparently drawing to a close. During the more than five years of destruction and privation accompanied by forcible or voluntary displacement of a large fraction of a populous continent's inhabitants there has been no pandemic of first magnitude. Gratifying though this is, the fact must not be taken to mean that the epidemic situation is as satisfactory as it was before the war, nor as indicating a favorable outlook for the first years of transition to stable peace. The absence of real disasters may be traced to the low endemic level of most diseases during the years preceding the war in conjunction with the advance of preventive medicine and the application on a large scale of its principles. On the other hand, caution against over optimism is dictated by the disastrous aftermath of World War I.

During the four years of World War I Europe witnessed a rise of the endemic level of infectious diseases, and there were various pestilential outbreaks, such as that of cholera in Galicia in 1915, which caused over 17,000 deaths. A devastating typhus epidemic broke out in Siberia in 1915, causing 150,000 deaths in six months, and there were severe typhus epidemics in Egypt. Moreover, typhus caused several hundred thousands of deaths in Rumania during the winter of 1917-1918. There were extensive smallpox epidemics in various countries. Nevertheless it was after the cessation of hostilities and following the disintegration of established government over wide areas that typhus, relapsing fever, cholera, smallpox, malaria, dysentery and typhoid swept across eastern Europe, leaving millions of victims, and made serious inroads also in southern and central Europe. Whether directly due to conditions of war or not, it was at the time of the armistice that the influenza pandemic struck, causing in less than half a year twenty million deaths throughout the world.

With World War II entering its final stage, civil administration is now in a fluid state in many areas and refugee movements are gathering momentum. These conditions, propitious to the propagation of epidemics, are likely to grow worse during the current year. They will further complicate the return to their native countries of millions of prisoners of war, shanghaied laborers, forcibly displaced people and other uprooted men, women and children, in themselves constituting grave potentialities as far as epidemics are concerned.

Appreciation of the problems at hand may be based on (1) the trend of epidemic diseases in recent years in areas for which fairly accurate epidemiologic data are available, (2) fragmentary information regarding the areas where no precise records of recent date exist and (3) various estimates of displaced persons. The latter problem, which has other angles than the epidemiologic, will not be dealt with in this summary.

It may be said at once that among the five pestilential diseases covered by the International Sanitary Conventions only louse borne typhus presents an immediate and grave danger to Europe. Cholera, which is a serious problem in Asia, has not appeared within recent years west of India and Afghanistan. Yellow fever seems hardly to have spread during the war and has not been observed north of the North African desert belt. It should be added however that, had no precautions been taken, the extension of these diseases would probably have been different.

As far as we know, plague has not been introduced into any European port during the war. Nevertheless this may happen at any time, as it did after World War I, because several large ports in North Africa and the Near East have become infected. The most important nearby foci are in the Suez Canal Zone and at Dakar. Although they are quiescent at present on account of the season, these foci may flare up again. Meanwhile infection has spread to other ports, such as Haifa and Jaffa in Palestine, Ferryville in Tunis, and Algiers and Oran in Algeria. The old plague centers in Morocco, especially at Casablanca, and in the Azores Islands have also shown renewed activity in recent years. The outbreak in the Suez Canal Zone from November 1943 to September 1944 was the worst on record, 712 cases being reported as against 359 in 1917. There were over 500 plague cases at Dakar in 1944, which is equal to the number notified in 1931, the worst year since 1920.

Europe has remained practically free from smallpox during the war except for the 1944 outbreak in Sicily and southern Italy and an extension of the Near East epidemic into European Turkey and the neighboring parts of Greece. The latter epidemic, which was of the classic type, has now come to an end. The Italian epidemic, the first case of which appeared in March 1944, has centered at Palermo and at Naples and vicinity. Although there have been some 1,500 cases all told, the epidemic is apparently not of prime importance because all cases have been of the mild type. Only six deaths were reported, all among debilitated children.

In this connection it may be of interest that mild type smallpox seems to have gained ground in French North Africa, while the classic type still prevails in the Near East. In the Iberian peninsula, where smallpox was widespread during the early years of the war, there are now only sporadic cases of variola minor.

The most encouraging element in the whole epidemic situation is that there were only 3 cases of smallpox in 1944 (7 cases in 1943) among the more than 200 million inhabitants of continental Europe outside the Soviet Union and the Mediterranean peninsular areas. In 1919 there were nearly 50,000 cases of smallpox in this area.

Typhus presents a far greater danger than smallpox. In certain areas severe epidemics are already under way, and in much larger areas the danger is potential because for several years there has been an insidious spread of sporadic infection throughout central Europe. It should also be remembered that North Africa and the Near East are just emerging from an epidemic wave extending from Morocco to Iran, which has been among the worst on record in several of the countries.

The Soviet Union was the principal sufferer from typhus following World War I but has apparently succeeded in keeping this disease under close control during the present war. The publication of records was discontinued, however, a couple of years before the outbreak of the war. In Poland, typhus is known to have been on the increase during the German occupation, but numerical indications are not available for the last four years.

Cases of Certain Epidemic Diseases Reported in Twelve Continental European Countries

Disease	Median, 1928-1938	Cases, 1943	1943 Incidence in Units of Pre-war Level
Cerebrospinal meningitis*	2,561	7,99	3.1
Poliomyelitis	4,546	11,292	2.5
Typhoid	28,681	44,316	1.5
Dysentery**	10,965	23,110	2.1
Diphtheria	168,354	501,911	3.0
Scarlet fever	176,276	566,398	3.2

* In fifteen countries.
** In eight countries.

There are three main epidemic foci of typhus in southeastern Europe: the Rumanian with center in Bessarabia and eastern Moldavia; the Subcarpathian with center in Subcarpathian Ruthenia and extending into northeastern Hungary; the Croatian with center in Bosnia and probably extending into Serbia. All of these foci were in rapid evolution last spring, and there was a serious epidemic in Croatia and Bosnia extending late into the summer. Information for recent winter months is not available for the Subcarpathian area. An epidemic reminiscent of the World War I disaster has broken out in Rumania. Unofficial information gives 30,000 cases in Moldavia alone, and the epidemic is likely to increase up to April or May. So far, this is undoubtedly the most serious epidemic outburst of any disease during the present war.

In recent years the endemic level has been rising also in Bulgaria and Greece, and typhus was epidemic in Turkey in 1943. On the other hand, the typhus epidemic which visited Spain in 1941 and 1942, causing over 11,000 cases, has now been reduced to an endemic level. The outbreak in and around Naples during the winter of 1943-1944 (somewhat over a thousand cases all told) was brought under control in the course of a few months, and at present there is hardly any typhus in Italy.

In Germany, where typhus was formerly unknown, there were over 5,000 cases in 1943, mostly among foreign workers. The cases were spread over the entire area of the reich as far west as Rhineland. Information for recent months is not available, but present conditions obviously favor the spread of infection.

The typhus free area of the European continent now consists only of the three Scandinavian countries, Finland, Switzerland and, aside from relatively rare sporadic cases, the Netherlands, Belgium and France.

With the exception of an outbreak in Tunis in March and April 1944 and the tick borne cases in Spain, relapsing fever, which followed on the great typhus epidemics of 1919-1921, has not been heard from during the present war.

The aforementioned diseases specially dealt with in the Sanitary Conventions, namely cholera, yellow fever, plague, smallpox and typhus, are international quarantine diseases not merely because they are the most dangerous but also because they are of limited geographic extension and their introduction into uninfected areas is consequently feared. Various other epidemic diseases, such as typhoid, diphtheria, scarlet fever and influenza, are numerically more important in Europe, but they are normally endemic in all countries. International transmission thus becomes of importance only when they develop particularly virulent strains locally or attain an unusually high incidence.

Apart from the menace of typhus, the most significant fact of the epidemic situation is that the incidence of all the common infectious diseases has doubled or trebled in that part of the European continent for which statistics are available, and this means chiefly among the resident population of the less desperately afflicted countries. The accompanying table, which covers mainly central, northern and western Europe, is based on the regular official returns of twelve countries where the public health services have never ceased to function and where the statistics may be considered reasonably accurate. Returns for 1943 have been used because the 1944 data are not yet complete. The prewar data used for comparison cover a period sufficient to include unfavorable years.

The significant fact brought out by the table is that there has been a heavy increase in the incidence of not merely some but of all these diseases. It is unusual that entirely unrelated diseases should reach a peak during the same year and on a whole continent. The increase has probably been even greater than shown because reporting is likely to have deteriorated in most countries, fewer physicians being available to notify civilian cases than in peacetime. Furthermore, there are excluded from the statistics the huge number of men in the armed forces and, in several countries, also certain categories of nonresident population. There is thus a greatly increased amount of infection of all kinds, which doubtless results also in an increased ratio of carriers. It is in this polluted atmosphere that the war will have to be wound up.

Efforts to control typhoid have been partly successful, and the increase of this disease has been the least spectacular among those shown in the table. However, the table does not include Italy, which in 1942 was responsible for one half of the typhoid cases reported in all of Europe outside the Soviet Union and the Iberian peninsula. The rate of increase is further lowered by the returns for Hungary, where the prewar level has been maintained by systematic vaccination. In other central European countries the incidence of typhoid has doubled, and in France it has almost trebled.

Typhoid remains as rare in the Scandinavian countries as in the United Kingdom; in a general way its incidence increases from north to south. While in Denmark and Sweden there was less than 1 case per hundred thousand inhabitants in 1943, there were 6 in the Netherlands, 10 in the prewar Germany, 27 in Bohemia-Moravia, 36 in France (highest in the south), over 200 in Spain and probably not less in Italy, and 133 in Greece, with only a fraction of the actual cases reported. Switzerland remained an area of low incidence. The problem of typhoid will naturally become more acute in areas where actual fighting has caused destruction of water supplies and the herding of refugees.

Paratyphoid fevers, on the other hand, are at least relatively more prevalent in the northern part of Europe, where cases are from two to five times more numerous than typhoid cases. In prewar Germany the score is about even. In southern Europe, on the other hand, paratyphoid cases are only a small fraction of the total enteric fever group.

Dysentery is perhaps to be feared even more than typhoid fever during the immediate postwar period. The figures for this disease in the table represent only the cases actually reported in greater Germany, Bohemia-Moravia, Hungary, Switzerland, the Netherlands and the three Scandinavian countries, and reporting of this group of diseases is everywhere defective. The fourteen-fold increase of dysentery cases over the prewar level which took place in the Netherlands suggests that only a fraction of the cases occurring elsewhere in central Europe have been notified. Fortunately the type most commonly encountered among the resident civilian population is the mild Sonne E. In the German army, however, Flexner and Hiss Y have prevailed, and there have been outbreaks of the Shiga type among prisoners of war. Their return from central Europe may therefore give rise to epidemics of severe types, especially should such return occur in the autumn. The spread of winter dysentery for some years past in the North Sea and Scandinavian areas is a new development the significance of which is not yet clear. Amebic dysentery seems nowhere to have attained epidemic proportions and is unimportant in northern and central Europe.

The "new" disease of this war has been epidemic jaundice (infectious hepatitis). From an obscure existence among the garrison of Malta and in a few German army units, it assumed proportions to interfere occasionally with military operations and spread among the civilian population from the Libyan desert to the North Cape. The disease was really not new but was known already from World War I, when at times it was confused with Weil's disease. It occurred also among civilians in various countries but had never been considered capable of setting up veritable epidemics. The reported incidence has for each of the last two years been as high as 1 per cent of the civilian population in Norway and 4 per cent in some of the provinces. Even higher rates of incidence have been reported in certain military units in North Africa. It appears to have been widespread in Germany, but, if it has been made notifiable, the number of cases has remained a secret. Epidemic jaundice is notifiable only in the three Scandinavian countries, Finland and Switzerland. About 65,000 cases were reported in these five countries in 1943, and returns for 1944 are, on the whole, not lower. The case mortality rate has fortunately, at least hitherto, been fairly low, usually ranging from 1 per thousand to 1 per cent, but there is some evidence that it increases with age. Epidemic jaundice is clearly a virus disease of an extremely high degree of infectivity and capacity for covering distances, which may have to do with the long period of incubation (three or four weeks). Since its potentialities are unknown and means of combating it have not so far been devised, this disease deserves to be closely watched.

Among other diseases of Mediterranean origin pappataci or sandfly fever has given some trouble in the Balkans and in Italy. Undulant fever, whether of the Mediterranean or the Bang type, does not seem to have increased to any noteworthy extent during the war.

During the twenty years between the two world wars poliomyelitis has slowly spread from north to south in Europe, moving by patches of varying intensity. During the war years this spread has apparently become accelerated. The incidence is considerably higher on the continent than in the British Isles. The most important poliomyelitis epidemics of 1943 occurred in Sweden, the Netherlands and central France. In 1944 Denmark, Sweden and Switzerland were the principal sufferers, and in the two former countries the outbreaks reached their peaks only in November.

As might be expected, cerebrospinal meningitis has been much above its normal level ever since the beginning of the concentration of troops leading up to the war. Since 1941, however, there has been a gradual decrease of the incidence, which, with minor exceptions, has constantly remained lower on the continent than in the British Isles.

Encephalitis lethargica has not been heard from, except for the usual sporadic cases.

So far diphtheria has turned out to be the leading epidemic disease of the war on the European continent as a cause both of morbidity and of mortality. It is estimated that there were at least one million cases in 1943 outside of the Soviet Union, and the case mortality rate can at present not be set at less than 5 per cent. In Germany alone nearly 300,000 cases were reported in 1943, with the rise continuing also in 1944, and there were 15,000 deaths from diphtheria in 1942. The incidence of carriers has increased enormously. The rise of diphtheria in Germany has been steady over a number of years, while in several other countries, and especially in Norway and the Netherlands, it has been explosive, attaining in 1943 respectively twenty-four and fourteen times the normal level. During the last three years there have been about 150,000 cases of diphtheria in the Netherlands. With a case mortality rate in that country of nearly 7 per cent, diphtheria has thus become one of the leading causes of death, running not very much behind tuberculosis in spite of the rapid increase of the latter disease. A severe epidemic is prevailing also in Finland. The contrast with the experience in England, where diphtheria has actually been reduced during the war years, is most striking. On the continent a reduction has been attained —through vaccination—only in Hungary. Denmark, Sweden and Switzerland have also maintained a relatively low incidence.

The most serious development of diphtheria, however, is not so much its spread as the change in type and its increasing gravity. The proportion of severe croupous cases has increased, and particularly noteworthy is the increase of cases refractory even to early serum treatment. In a series of diphtheria autopsies

performed in Germany 64 per cent showed interstitial myocarditis, while this condition had formerly been found in only one fourth of the postmortems. There has also been a shifting of the age incidence. At Rostock, in 1943, 30 per cent of the diphtheria deaths were over 15 years of age (6 per cent before 1940) and 9 per cent over 60. Diphtheria has been among the most important causes of fatal illness in the German army, and it has also proved a fatal complication of typhus as well as of chest wounds.

Scarlet fever has spread almost as much as diphtheria and with few exceptions its incidence is from two to five times the prewar level. Nevertheless there has been no explosive epidemic comparable to the diphtheria outbreaks in the Netherlands and in Norway. There seems to have been no change in type or gravity of the disease. A heavy increase of measles has also been noted, especially during the earlier years of the war.

The only important epidemic disease which seems to have remained unaffected by the war is influenza. The usual winter waves have come and passed, the most recent reaching its peak during the early part of the winter 1943-1944. In spite of abnormal living conditions, none of them attained the gravity of the three or four most serious interwar epidemics. The change from influenza B to influenza A reported to have taken place in England between the 1942-1943 outbreak and that of 1943-1944 does not seem to have had any visible effect on the mortality. Nevertheless the danger of major epidemics cannot be entirely disregarded.

In addition to the epidemic perils, the increasing incidence of endemic diseases, such as malaria, syphilis and tuberculosis, must be carefully considered. Malaria is the leading cause of morbidity in a large part of the Mediterranean basin, and it is reported to have assumed epidemic proportions in Greece during the last couple of years. The areas of high endemicity in the Balkans and in Italy have probably by this time returned to their lamentable precontrol state, and further spread must be counted on, especially in view of the forced migrations. Falciparum infection predominates in autumn in the truly Mediterranean countries, while farther north vivax malaria prevails. The latter form may extend northward into Europe as it did after the last war.

Reports relating to the Scandinavian countries, Finland, France and Germany indicate that the incidence of syphilis has increased from three to nine fold, and the achievements of the twenty years of peace in venereal disease control have practically been wiped out. While the spread of gonorrhea was checked for some years by successful sulfonamide treatments, virulent sulfonamide resistant strains are now reported to be developing and spreading. Penicillin treatment has not yet become generalized.

Infectious skin diseases, such as scabies, have also spread at an extraordinary rate, but the removal of soap from the list of luxuries should bring about a downward trend.

The war had no effect on the tuberculosis mortality in 1939 and 1940, but an increase began in 1941 in several countries and became more or less general from 1942 and on. The situation is now much the same as during and immediately after World War I, except that the increase this time started from a lower level. The part of the improvement gained from 1920 to 1939 which has been lost varies greatly. Great Britain, the Scandinavian countries and Switzerland have withstood the years of trial remarkably well, although their tuberculosis problems may require increased attention during the first postwar years. The number of tuberculosis cases has increased greatly in France, Belgium, the Netherlands, Germany, Austria, Czechoslovakia and Hungary, and it has doubled in many parts of this area. Among these countries the Netherlands is undoubtedly the worst sufferer. The Balkans, where the tuberculosis mortality was high also before the war, are probably back to the conditions of twenty-five years ago. In Italy the situation is likely to become worse than ever before, and Poland faces an unprecedented calamity.

In general, the epidemic outlook is not unlike the forecast which might have been made this day twenty-seven years ago. As then, the general endemic level of nearly every kind of infection has risen and serious epidemics have already appeared. In February 1918 no one could have forecast the influenza pandemic, but other developments might have been foreseen had sufficient information been currently available. Unpredictable epidemics may occur, war or no war, but our knowledge of the existing situation is far more complete and up to date than then. In several ways the outlook is darker than in 1918 because destruction of buildings and displacement of persons are far more widespread than during World War I. On the other hand, the endemic level was lower to start with in 1939 than it was in 1914, and the world is now better equipped to deal with many of the important infectious diseases.

On the public health front World War I lasted not four but more nearly ten years. However, it was gloriously won. Many years of effort in combating infectious diseases have once more been lost as far as Europe is concerned. To make up for backsliding will take several years after the cessation of active hostilities, but the public health profession and services can win their war now as then.

The foregoing summary, although cursory for reasons of space, is based entirely on reliable official information, and no representations by unqualified informers having an interest in magnifying the plight of their countries have been taken into account. Reviews dealing in greater detail with each disease will appear in subsequent numbers, as will also the statistics relating to these diseases. One of the tasks of this bulletin is to make accessible in one place the records gathered in different parts of the world and by various national and international services. Beginning to appear in the next number, these statistics will be gradually developed so as to cover in the end all infectious diseases of interest. The reviews will be informal and unrelated to any action under the International Sanitary Conventions, as they are prepared solely for the convenience of health officers and others concerned with the rise and fall of infectious disease.

In 1918, beyond the notification of plague, cholera and yellow fever, there was no international clearing house for epidemiologic information and no publication giving current records of epidemic diseases. This task was taken up by the Epidemiological Intelligence Service of the League of Nations only in 1922, that is, after the postwar epidemics had passed their peaks. Epidemiologists realized already then that such a service would have been still more helpful had it been established early in that war. It is the hope of the UNRRA Health Division that this new venture, which will reach its full development only in the course of some months, will complete and coordinate existing undertakings in this field.

THE SURGICAL TREATMENT OF MALFORMATIONS OF THE HEART

IN WHICH THERE IS PULMONARY STENOSIS OR PULMONARY ATRESIA

ALFRED BLALOCK, M.D.
AND
HELEN B. TAUSSIG, M.D.
BALTIMORE

Heretofore there has been no satisfactory treatment for pulmonary stenosis and pulmonary atresia. A "blue" baby with a malformed heart was considered beyond the reach of surgical aid. During the past three months we have operated on 3 children with severe degrees of pulmonary stenosis and each of the patients appears to be greatly benefited. In the second and third cases, in which there was deep persistent cyanosis, the cyanosis has greatly diminished or has disappeared and the general condition of the patients is proportionally improved. The results are sufficiently encouraging to warrant an early report.

The operation here reported and the studies leading thereto were undertaken with the conviction that even though the structure of the heart was grossly abnormal, in many instances it might be possible to alter the course of the circulation in such a manner as to lessen the cyanosis and the resultant disability. It is important to emphasize the fact that it is not the cyanosis, per se, which does harm. Nevertheless, since cyanosis is a striking manifestation of the underlying anoxemia and the compensatory polycythemia, a brief discussion of the causes of cyanosis and the factors operative in congenital malformations of the heart is essential in order to understand the principles underlying the present operation.

Cyanosis is due to the presence of reduced hemoglobin in the circulating blood. It is a well established fact that there must be at least 5 Gm. of reduced hemoglobin per hundred cubic centimeters of circulating blood for cyanosis to become apparent. It has long been recognized that one of the principal factors in the production of cyanosis in malformations of the heart is the direct shunting of venous blood into the systemic circulation. Lundsgaard and Van Slyke [1] in their classic studies on the causes of cyanosis showed that there were four important factors in the production of cyanosis: the height of the hemoglobin, the volume of the venous blood shunted into the systemic circulation, the rate of utilization of oxygen by the peripheral tissues and the extent of the aeration of the blood in the lungs. Their studies demonstrated the great importance of pulmonary factors. The extent of the oxygenation of the blood in the lungs clearly depends on the vital capacity of the individual, the rate of the flow of blood through the lungs, the partial pressure of the oxygen in the inspired air and also on specific pulmonary factors, which these authors designated as the a factor. These investigators showed that in most, if not in all, cases in which there was a pronounced polycythemia, secondary changes occurred in the lungs of such a nature that all of the blood that passed through the lungs was no longer in effective contact with the oxygen in the alveoli. The importance of this factor can be demonstrated by the prolonged inhalation of oxygen. In almost every case in which there is polycythemia, cyanosis can be greatly lessened by the prolonged inhalation of oxygen. The fact that all of the blood which circulated through the lungs is not fully oxygenated made it seem improbable that if more blood circulated through the lungs a larger proportion of the blood would be oxygenated. Thus the demonstration of the a factor completely overshadowed another vitally important factor, namely the volume of blood which reaches the lungs for aeration.[1a]

Expressed in the simplest terms, the circulation of the blood through the lungs after birth is essential for life; any one deprived of such circulation dies. Indeed there is a point at which, even though none of the other pulmonary factors are operative in the production of cyanosis and all of the blood that passes through the lungs is fully oxygenated, the volume of blood that reaches the lungs for aeration and hence the volume of oxygenated blood returned to the systemic circulation is insufficient for the maintenance of life. For example, in all cases of pulmonary atresia in which the circulation to the lungs is by way of the ductus arteriosus the closure of the ductus arteriosus renders the condition incompatible with life.

Undoubtedly the importance of the diminution of flow of blood to the lungs has not been fully appreciated, mainly because studies on the nature of cyanosis have been made on older children and young adults, and it is only when this factor is not of vital importance that the individual has survived to that age. All infants with pulmonary atresia with or without a right ventricle and with or without dextroposition of the aorta, in whom the closure of the ductus arteriosus cuts off the circulation to the lungs, die at an early age. In cases of complete pulmonary atresia death occurs before the complete cessation of circulation of blood through the lungs; hence in such cases there is always slight patency of the ductus arteriosus. In cases of a tetralogy of Fallot with an extreme pulmonary stenosis, the ductus arteriosus may become entirely obliterated before death.

There are two different types of congenital malformations which illustrate the importance of the volume of the pulmonary circulation in the production of cyanosis. The first is that of a single ventricle with a rudimentary outlet chamber in which it is common to find that one great vessel is given off from the common ventricle and one from the rudimentary outlet chamber. Usually the vessel which arises from the common ventricle is of normal size and that from the rudimentary outlet chamber is diminutive in size.[2] If the great vessels occupy their normal positions, the aorta arises from the common ventricle and is of large caliber, whereas the pulmonary artery which arises from the rudimentary outlet chamber is of small caliber. Under such circumstances a large volume of blood goes to the systemic circulation and only a small volume of blood goes to the lungs. Consequently a large volume of unoxygenated blood is mixed with a small volume of oxygenated blood and cyanosis is intense.[3] When, however, the great vessels are transposed and the pulmonary artery is large and the aorta is small, a large volume of blood goes to the lungs for aeration. Under these circumstances a large

volume of oxygenated blood is mixed with a relatively small volume of venous blood and cyanosis is minimal or absent, as in the case reported by Glendy and White.[4]

The same phenomenon is also seen in cases of truncus arteriosus. When the pulmonary arteries are given off directly from the aorta there is adequate circulation to the lungs, and cyanosis is minimal or absent. In contrast to this, if the pulmonary artery fails to arise from the heart or connect with the aorta and the circulation to the lungs is by way of the bronchial arteries only a small volume of blood reaches the lungs for aeration, and cyanosis is intense.[5]

The importance of adequate circulation to the lungs is further illustrated in the anomalies of the venous return in which all of the pulmonary veins drain into the right auricle; consequently within this chamber there is complete admixture of venous and arterial blood. In such cases a large volume of blood goes to the lungs for aeration and a large volume of oxygenated blood is returned to the right auricle. There is great right-sided cardiac enlargement but no cyanosis until the terminal collapse of the circulation.[6]

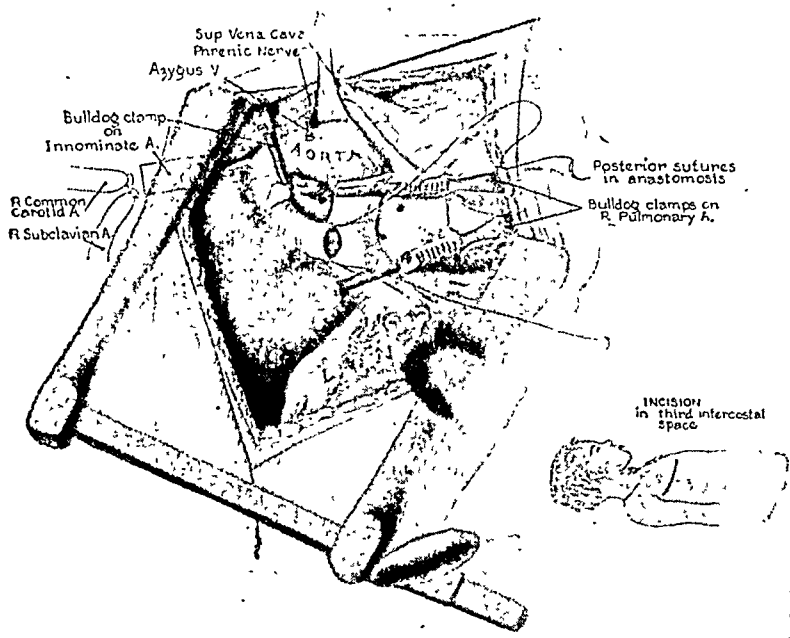

Fig. 1.—General exposure of the operative field on the right side. The end of the innominate artery is being anastomosed to the side of the right pulmonary artery. The posterior row of sutures is complete. The anterior row has not been inserted.

These observations clearly indicate that many gross malformations of the heart are compatible with life provided there is adequate circulation to the lungs, and furthermore that lack of circulation to the lungs is the primary cause of death in many infants with congenital malformations of the heart. Furthermore, one of us (H. B. T.) has seen several infants with pulmonary stenosis in whom cyanosis was not apparent until the ductus arteriosus closed. In other words, there was no "visible" cyanosis while the circulation to the lungs was adequate. It was an appreciation of these facts (H. B. T.), together with an extensive previous experience with the experimental use of large arteries for the purpose of conducting blood to sites not usually supplied by such vessels, that led to the development of the clinical work recorded in this paper.

The feasibility of anastomosing a systemic artery to one of the pulmonary arteries in experimental animals has been demonstrated by Levy and Blalock.[7] As far as we are aware, this was the first time that both the course and the function of a large artery were altered. Similar experimental alterations were produced subsequently by Eppinger, Burwell and Gross[8] and by Leeds.[9] Blalock and Park[10] have reported the suturing of the severed proximal end of the subclavian artery to the aorta as a means for conducting blood beyond the point of an experimental coarctation of the aorta. In unreported observations by Kieffer and Blalock the divided proximal end of the splenic artery has been connected to the distal end of the divided left renal artery and there has been no evidence of renal failure even though the right kidney was removed. In other words, arterial anastomoses have been performed in animals for the purpose of conducting blood to sites other than those ordinarily supplied by these vessels.

Before undertaking the operations on patients, many experiments were performed in an effort to produce pulmonic stenosis in dogs. This work met with little success. Finally, in an effort to cause a significant decrease in the oxygen saturation of arterial blood, one or more lobes of the lungs were removed from each side of the chest, and the main arteries and veins of these lobes were connected end to end by suture. In other words, bilateral pulmonary arteriovenous fistulas were produced. These procedures resulted in some instances in a pronounced reduction in the oxygen saturation of the arterial blood. As the result of an artificial patent ductus arteriosus made in two such experiments, there was a significant increase in the arterial oxygen saturation. Although this experimentally produced condition is quite different from that seen in patients, it is of interest that the making of an anastomosis between systemic and pulmonary arteries caused an increase in the oxygen saturation of the arterial blood despite the fact that several lobes of the lungs had been removed.

Since the present operation was devised to compensate for an inadequate flow of blood to the lungs, it seemed desirable that the anastomosis be made in such a manner that the blood from the systemic artery would be able to reach both lungs. It is obvious that the suture anastomosis could not be made to the main pulmonary artery since occlusion of this vessel for more than a few minutes causes death. It appeared, therefore, that the anastomosis should be made just distal to the division of the main pulmonary artery and, furthermore, that the side of the chosen vessel should be used in order that the blood might flow to both lungs.

It was our original idea that the subclavian artery would be the ideal systemic vessel and that after division

of this artery its proximal end should be anastomosed to the side of the left pulmonary artery. The fortunate experience to be reported in regard to the second patient has led us to prefer the use of the innominate artery in patients with a severe degree of anoxemia. This patient had a right aortic arch, and the innominate artery was directed to the left side of the chest and neck.

Although there were slight variations in each of the operations, the major features were as follows: Light general anesthesia was produced by the inhalation of ether or cyclopropane. The patient was placed on the table on his back with a slight elevation of that side of the chest which was to be exposed. The patient's arms were strapped in place along his sides. The operation was performed on the right or left side depending on the position of the great vessels and the artery to be used in the anastomosis. The incision was made in the third interspace and extended from the lateral border of the sternum to the axillary line. The pleural cavity was entered and the third and fourth costal cartilages were divided. A rib spreader was introduced and a good exposure of the upper half of the pleural cavity was obtained. This area is shown in figure 1. The right or left pulmonary artery was then exposed and the vessel was dissected from the adjacent tissues for as great a distance as possible. This was more difficult on the right side than on the left and it was necessary to ligate and divide the azygos vein and to retract the superior vena cava medially. Nothing further was done to the pulmonary artery at this time. Attention was then focused on the systemic artery which was to be anastomosed to one of the pulmonary arteries. The subclavian or innominate artery was dissected free of the adjacent tissues and the vessel chosen was occluded temporarily at the point where it arose from the aorta by the use of a bulldog arterial clamp. In cases in which the innominate artery was chosen, its branches (subclavian and common carotid) were ligated at their origins and the innominate artery was cut across just proximal to the ligatures. In the 1 case in which the left subclavian artery was used for the anastomosis to the pulmonary circulation it was necessary to divide the thyrocervical trunk, the vertebral artery and the internal mammary artery in order to gain access to a sufficient length of the vessel. After the removal of some of the adventitia from the systemic vessel the pulmonary artery was further prepared for the anastomosis. A bulldog arterial clamp was placed on the left or right pulmonary artery just distal to the point of division of the main pulmonary artery. A second bulldog arterial clamp was placed on the left or right pulmonary artery just proximal to the point where the vessel gave off a branch to the upper lobe of the lung. A transverse opening was made into the side of the pulmonary artery approximately midway between these two arterial clamps. This opening was of about the same diameter as that of the end of the systemic vessel which was to be anastomosed to it. It must be emphasized that the pulmonary artery was not occluded until all preparations for the anastomotic procedure had been made.

The anastomosis between the end of the systemic artery and the side of the pulmonary artery was carried out in the following manner: Fine silk on a curved needle was used as suture material. Before placing the posterior row of sutures, a stay suture was placed at one end. This was followed by the insertion of a running suture, which was not drawn taut until the greater part of the posterior row had been placed. The stay suture was then tied and the running suture was in turn tied to the stay suture. The posterior row was completed and was tied to another stay suture. The anterior row consisted of a simple through and through

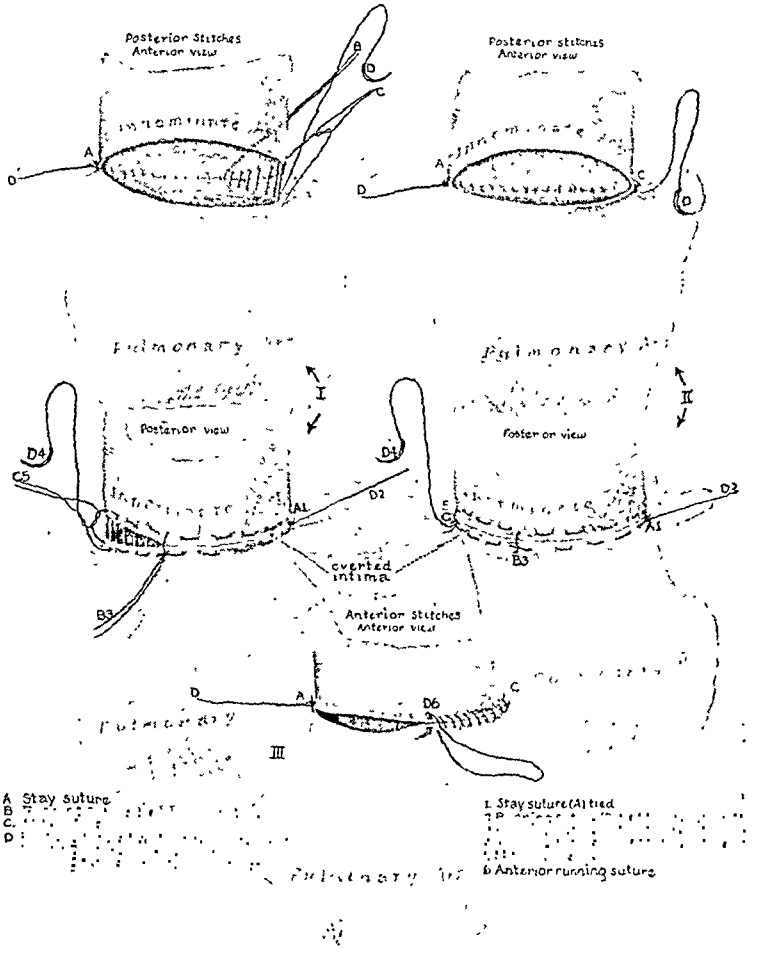

Fig. 2.—Details of the method by which the end of a systemic artery is anastomosed to the side of one of the pulmonary arteries.

continuous suture which approximated intima to intima. The anastomosis is shown diagrammatically in figure 2. The bulldog clamps were then removed from the pulmonary artery, and this was followed by removal of the clamp from the systemic vessel. If bleeding from the suture line did not cease spontaneously, it was stopped by the use of additional sutures. The lung was reexpanded and the incision in the chest wall was closed. Two encircling sutures of braided silk were used for approximating the third and fourth ribs. The soft tissues of the chest wall were closed in multiple layers with interrupted silk sutures.

There follows a detailed report of the 3 cases in which such an operation has been performed.

REPORT OF CASES

CASE 1.[11]—*History.*—E. M. S., a girl, was born prematurely in the obstetric service of the Johns Hopkins Hospital on Aug. 3, 1943. Her birth weight was 1,105 Gm. A systolic murmur was noted shortly after birth. Slight cyanosis was noted on the fourth and fifth days of life; this subsequently disappeared. The baby gained weight slowly and was finally discharged at 4 months of age weighing 2,900 Gm. After discharge the baby was followed in the dispensary. She was at first thought to have a simple interventricular septal defect, because the heart was normal in size and there was no cyanosis.

At 8 months of age the baby had her first attack of cyanosis, which occurred after eating. It was then for the first time that we thought she had a tetralogy of Fallot and not a simple interventricular septal defect. It soon became evident that cyanosis was increasing. It seemed probable that this increase in cyanosis was due to the fact that the ductus arteriosus was undergoing obliteration and thereby lessening the circulation to the lungs. By March 1944 it was obvious that the baby had a serious congenital malformation of the heart. After eating she would become deeply cyanotic, roll up her eyes, lose consciousness and appear extremely ill. Fluoroscopy showed that the heart was slightly enlarged; there was no fulness

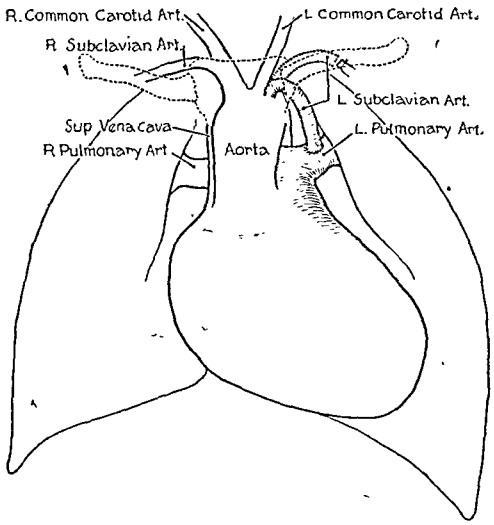

Fig. 3 (case 1).—Procedure used. The end of the left subclavian artery was anastomosed to the side of the left pulmonary artery.

in the region of the pulmonary conus. In the left anterior oblique position the right ventricle appeared slightly enlarged and the pulmonary window was abnormally clear. The clinical diagnosis was tetralogy of Fallot with a severe degree of pulmonary stenosis.

On June 25, 1944 she was first admitted to the Harriet Lane Home. Physical examination showed that she was poorly nourished and poorly developed. She had a glassy stare. Her lips were cyanotic. The heart was slightly enlarged and there was a harsh systolic murmur best heard along the left sternal border. The liver was at the costal margin. The baby was given oxygen and phenobarbital but remained very irritable and would become intensely cyanotic when taken out of the oxygen tent. During her three weeks' stay in the hospital she gained 200 Gm. and weighed 4.66 Kg. on discharge. She was sent home because it was felt that her condition was hopeless.

She was followed in the cardiac clinic for three months, during which time she showed increasing cyanosis and failed to gain weight. She was readmitted on October 17 because of increasing spells of cyanosis, coma and great venous distention of the head and body.

The weight on admission was 4.6 Kg. The venous distention was so great that the possibility of a subdural hydroma or hematoma was considered. Subdural tap was performed, with the removal of 8 cc. of clear fluid from the right side and a small amount of bloody fluid from the left.

The size of the heart as seen in the anteroposterior view was essentially the same as noted previously. There was still a harsh systolic murmur. In the left anterior oblique position the contour of the heart appeared as a little round ball with a narrow aorta and a clear pulmonary window (fig. 4); this, we believe, is characteristic of a very severe tetralogy of Fallot with a functional pulmonary atresia, that is, a pulmonary stenosis which is so extreme that the condition is not long compatible with life.[2] It was questioned at that time whether in addition to the malformation of the heart she suffered from mental retardation.

During the next six weeks she refused most of her feedings she lost weight and just before operation weighed only 4 Kg. The red blood cell count, which had been 7,000,000 on admission, had fallen to 5,000,000. Cyanosis was proportionally less conspicuous; indeed, at times while lying quietly, cyanosis was not visible. The clinical diagnosis was again tetralogy of Fallot which was so severe that the baby's condition was becoming critical.

Operation.—This was performed on November 29. The procedure consisted in the anastomosis of the divided proximal end of the left subclavian artery to the side of the left pulmonary artery, as shown diagrammatically in figure 3. The anesthetic agent was administered by Dr. Merel Harmel.

Under ether and oxygen anesthesia, administered by the open method, an incision was made on the left side of the chest extending from the edge of the sternum to the axillary line. The pleural cavity was entered through the third interspace. The left lung appeared normal. No thrill was felt on palpating the heart and pulmonary artery. The left pulmonary artery was identified and was dissected free of the neighboring tissues. It appeared to be of normal size. The superior pulmonary vein, on the other hand, seemed considerably smaller than normal. The left subclavian artery was identified and was dissected free of the neighboring tissues. In order to secure access to a sufficient length of this vessel it was necessary to ligate and divide the vertebral artery, the internal mammary artery and the thyrocervical axis. A bulldog arterial clamp was placed on the subclavian artery at a point just distal to its origin from the aorta. The subclavian artery was ligated distal to the point at which the thyrocervical trunk had been ligated and divided, and the vessel was cut across just proximal to this ligature. Two bulldog clamps were placed on the left pulmonary artery, the first clamp being placed at the origin of the left pulmonary artery and the second clamp being placed just proximal to the point where the pulmonary artery entered the lung. There was ample space between these two clamps for our purpose. A small transverse incision was made in the wall of the pulmonary artery at a point approximately equidistant between the two clamps. By the use of china beaded silk on fine needles an anastomosis was performed between the end of the left subclavian artery and the side of the left pulmonary artery. There was practically no bleeding following the removal of the clamps.

From a technical point of view the anastomosis seemed to be satisfactory. The main cause for concern was the small size of the left subclavian artery. It was somewhat disturbing that one could not feel a thrill in the pulmonary artery. We were confident, however, that the anastomosis was patent. A small quantity of sulfanilamide was placed in the left pleural cavity and the incision in the chest wall was closed. The patient was given 200 cc. of isotonic solution of sodium chloride and 50 cc. of blood during the operative procedure. The operation required slightly less than an hour and a half and the left pulmonary artery was occluded for approximately thirty minutes. The patient's condition at the end of the operation seemed moderately good.

Postoperative Course.—This was stormy. The patient's left arm and hand were observed frequently. The radial pulse was not palpable and this extremity was cooler than the opposite one, but it was apparent that the circulation was adequate to maintain life of the part. The child suffered from repeated bilateral pneumothoraces, and frequent aspirations were required.

11. This case was discussed briefly at the meeting of the Southern Surgical Association, Dec. 5, 1944, in a paper by Dr. Arthur Blakemore.

Probably the pneumothorax on the right was due to the use of too great pressure in the reexpansion of the left lung at the completion of the operative procedure. As it was found to be a positive pressure pneumothorax, constant suction was exerted through a needle inserted into the right pleural cavity. Had it not been for the excellent care given by the pediatric house staff, particularly Dr. Kaye, Dr. Whitemore, Dr. Steinheimer, Dr. Hammond, Dr. Gilger and Dr. Helfrick, in all probability the child's life would not have been saved.

The child's condition began to improve two weeks after operation. Thereafter further aspirations of the pleural cavity were not required. The occasions on which the patient would become cyanotic became less frequent. Otitis media developed and responded to treatment. The systolic murmur became somewhat louder, but a continuous murmur could not be heard in the pulmonary area.

The patient was discharged from the hospital on Jan. 25, 1945, almost two months after the day of operation. Her condition was considerably better than it had been before operation. More recent follow-up studies have shown that she is gaining weight and that she is only occasionally cyanotic. If the cyanosis increases, it may be necessary to perform a similar operation on the opposite side. Roentgenograms of the patient's heart both before and after operation are shown in figure 4.

It is unfortunate that we do not have a quantitative degree of improvement such as might have been afforded by determinations of the oxygen saturation of the arterial blood. In view of the small size of the child we did not feel warranted in doing arterial punctures. The clinical improvement, however, has been striking. The baby takes her feedings well, is alert and active and has gained a kilogram in weight (that is, 25 per cent of her former body weight).

CASE 2.—*History.*—B. R., a white girl born July 9, 1933, was first seen at the Harriet Lane Home at 9 years of age, referred by Dr. Dexter Levy of Buffalo. The patient was cyanotic at birth. The birth weight was 6½ pounds (2,955 Gm.). She was breast fed for six months. In infancy she gained extremely slowly. She had erysipelas at 1½ years of age, a septic sore throat at 4½ years of age, chickenpox at 7 years, measles at 8 years and mumps at 9 years.

The patient was first seen in the Harriet Lane Home on Feb. 13, 1943. She was intensely cyanotic, became dyspneic on slight exertion and would constantly squat to get her breath. There was intense cyanosis and clubbing of the fingers and the toes. The buccal mucous membranes were of a deep mulberry color. There was suffusion of the conjunctiva. The chest was barrel shaped. Her heart was within normal limits in size. There was no thrill over the precordium. On auscultation there was a harsh systolic murmur which was maximal low down in the third and fourth interspaces. The murmur was much louder in the recumbent position than in the erect position, and louder when she bent forward than when she tried to sit erect. The murmur was not widely transmitted and was not audible in the back. The second sound at the base was pure. The lungs were clear. The liver was at the costal margin and the spleen was not palpable. The femoral arteries were readily palpable. The extremities, as previously mentioned, showed intense cyanosis and pronounced clubbing. At this time she climbed half a flight of stairs and walked, almost ran, leaning forward, 60 feet to her room, and then fell forward on the bed and lay in a knee-chest position, panting heavily and without speaking for half an hour.

The red blood cell count was 8,700,000; the hemoglobin was 25 Gm.; the hematocrit reading was 78.

The electrocardiogram showed a normal sinus mechanism, PR interval of 0.16 second, normal upright T waves in all four leads, and considerable right axis deviation.

X-ray examination and fluoroscopy showed the heart to be of normal size with a concave curve at the base to the left of the sternum (fig. 6). To the right of the sternum the superior vena cava cast a wide ribbon-like shadow. After the administration of barium, the aorta was seen to indent the esophagus to the left on its right margin. Examination in the left anterior oblique position showed that the right ventricle was not greatly enlarged; indeed, the left ventricle appeared larger than the right ventricle. The esophagus was seen to be indented by the aorta in the left anterior oblique position; in the right anterior oblique position its descent was independent of the aorta. There was no enlargement of the left auricle.

The clinical diagnosis was an extreme tetralogy of Fallot with a right aortic arch.

On Jan. 6, 1945 the patient returned for a check-up and because her parents wished to discuss the possibility of operation. The physical findings were essentially the same as previously noted but she was even more severely incapacitated. She could not walk 30 feet without exhaustion, and she panted when she moved from a wheel chair to the examining table. The fluoroscopic findings were essentially the same as noted previously except that the shadows at the hili of the lungs were more conspicuous. There were, however, no pulsations visible in this region.

The patient returned on January 29. Studies on the arterial blood are recorded in table 1.

A sample of venous blood showed that the red blood cell count was 7,500,000, the hemoglobin was 24 Gm., the hematocrit reading was 71 (Wintrobe) and the white blood cell count was 5,200. The electrocardiogram was essentially the same as that taken in 1943. A roentgenogram of the heart showed a small heart with a right aortic arch. The maximal right diameter was 4 cm. and the maximal left was 7 cm. The total transverse diameter was 26 cm. The cardiothoracic ratio was 42.4.

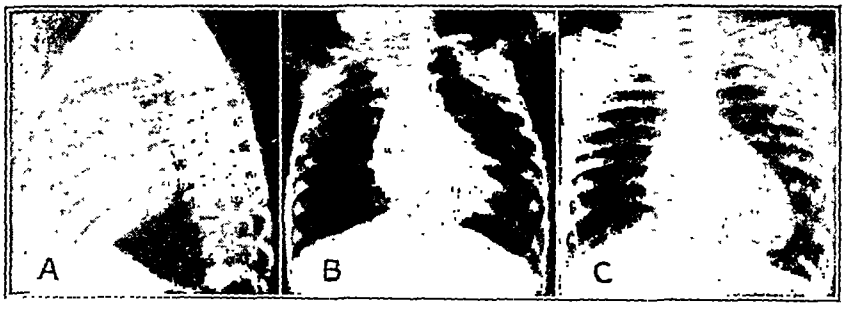

FIG. 4 (case 1).—Appearance before and after operation: *A*, left anterior oblique view before operation; *B*, anteroposterior view before operation; *C*, anteroposterior view after operation.

Operation.—This was performed on February 3. The procedure consisted in anastomosing the divided proximal end of the innominate artery to the side of the left pulmonary artery. This is shown diagrammatically in figure 5. The anesthetic agent was administered by Dr. Austin Lamont.

TABLE 1.—*Studies on Arterial Blood (Case 2)*

Cyclopropane with a high percentage of oxygen was administered through an endotracheal tube. The incision extended from the left costal margin to the anterior axillary line. The pleural cavity was entered through the third interspace. There were no adhesions between the lung and the chest wall, and the lung looked normal. Although the surgeon had been informed by his pediatric colleague that this patient almost

certainly had a right aortic arch, no special thought was given to the fact, and it caused some surprise when it was noted that the aorta was not on the left side. It was fortunate, however, that the incision had been made on the left because this allowed the use of the innominate artery rather than the subclavian artery. There was a very tortuous artery, which

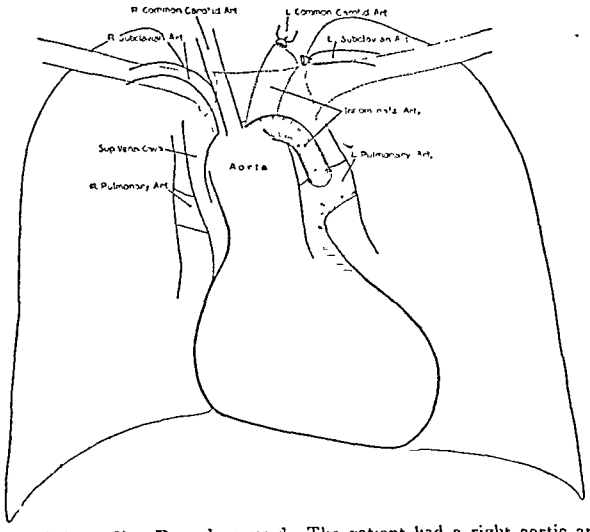

Fig. 5 (case 2).—Procedure used. The patient had a right aortic arch, and the innominate artery was directed to the left. The end of the innominate artery was anastomosed to the side of the left pulmonary artery.

was lying anterior to the vertebral column and which appeared to run from the region of the hilus of the lung toward the upper part of the left pleural cavity. Compression of this vessel indicated that the blood was flowing from above downward. It is believed that this vessel was a large accessory bronchial artery. It was estimated that the lumen of this artery was approximately 3 mm. in diameter. Still another abnormal finding was the large size of the posterior portions of the intercostal arteries. It seems likely that these vessels were also supplying blood to the hilus of the lung. The evidence of extensive collateral circulation led us to believe that we were probably dealing with a case of complete pulmonary atresia.

The innominate artery was located and dissected free of the surrounding tissues. The encouragement of the first assistant, Dr. William Longmire, played no small part in the continued effort to find a large systemic artery. A bulldog arterial clamp was placed on the innominate just distal to its origin from the aorta. The subclavian and common carotid arteries were ligated near their points of origin from the innominate. The innominate artery was divided just proximal to these ligatures. It was estimated that the diameter of the lumen of the innominate artery was approximately 1.3 cm. The left main pulmonary artery was then prepared for the anastomosis. A bulldog clamp was placed just distal to the origin of this vessel from the main pulmonary artery, and a second clamp was placed proximal to its entrance into the lung. A transverse opening was made into the lumen of the vessel midway between the two clamps. A suture anastomosis was performed between the end of the innominate artery and the side of the left pulmonary artery. The length of time that the left pulmonary artery was occluded was fifty to sixty minutes. The bulldog clamps were removed. There was bleeding from one point, which was controlled by an additional suture. An easily palpable thrill was felt in the pulmonary artery both proximal and distal to the anastomosis. The pulmonary artery seemed to be considerably larger than before this new current of systemic blood was admitted to it. The systemic arterial pressure was 110 systolic and 70 diastolic at the time that the arterial clamps were removed. Immediately following the removal of the clamps the systemic pressure declined 30 mm. of mercury. There followed a rise in systolic pressure of 20 mm. of mercury, but the pressure then declined gradually during the next thirty minutes until it reached 60 systolic and 30 diastolic. The pulse rate during this time rose from 72 to 120 per minute.

After the completion of the anastomosis and the removal of the clamps, several grams of sulfanilamide were placed in the pleural cavity. The left lung was partially inflated by the use of positive pressure, and the incision in the chest wall was closed. The patient was given a slow continuous intravenous drip of isotonic solution of sodium chloride during the operation and her condition at the end of the operation appeared to be satisfactory.

The operation required two hours and forty minutes. A considerable part of this time was consumed in studying the tortuous vessel which was seen above the hilus of the lung and also in trying to locate the innominate artery.

The patient awakened from the anesthesia a short time after the closure of the incision. She could move the left arm without difficulty. The left arm and hand were slightly cooler than the right, but it was evident that the circulation was adequate to maintain life. There was no evidence of a cerebral disturbance as the result of the ligation of the common carotid. No pulse could be felt in the left arm or the left side of the neck and face.

Postoperative Course.—This was smooth. There was no vomiting following operation, and fluids were taken by mouth. She was placed in an oxygen tent. The administration of penicillin was started immediately after operation and was continued for nine days. The left pleural cavity was aspirated twenty-four hours after operation; 250 cc. of air and 70 cc. of blood were removed. There were no other thoracenteses. Although a thrill was palpable at the site of the anastomosis immediately on release of the bulldog clamps, no murmur was audible immediately after the chest was closed. By the second evening a faint diastolic murmur was audible over the base and at the apex. By the third postoperative day an extraordinarily loud continuous murmur was audible throughout the chest on both the right and the left side. The oral administration of dicumarol was begun on the fourth postoperative day; 50 to 200 mg. was given daily for several weeks. Prothrombin determinations were performed daily. The dose of dicumarol was such as to keep the clotting time of the patient's blood approximately twice that of the normal control.

Femoral arterial punctures were performed on the ninth and twenty-sixth postoperative days. The results of the analyses are given in table 1. Before operation the red blood cell count was 7,500,000, the hemoglobin 24 Gm. and the hematocrit reading 71. Three days after operation the red blood cell count had decreased to 6,000,000, the hemoglobin to 19 Gm. and the hematocrit reading to 61. By the twenty-first day the red blood cell count was 6,000,000, the hemoglobin was 17.5 Gm. and the hematocrit reading was 55.

A roentgenogram of the heart taken ten days after operation showed that the heart had increased in size; that taken twenty-one days after operation revealed no further increase in size.

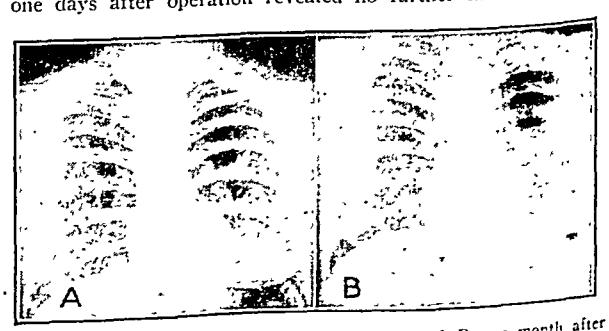

Fig. 6 (case 2).—Heart *A*, before operation and *B*, one month after operation.

Indeed, the heart was a trifle smaller than on the previous date. Roentgenograms of the heart before and after operation are shown in figure 6. Before operation the cardiothoracic ratio was 42.4 and three weeks after operation it was 44.7. The electrocardiogram showed no change (fig. 7). The stethocardiogram showed a continuous murmur (fig. 8). There was a significant increase in the pulse pressure. The preoperative arterial pressure had been 110 systolic and 90 diastolic. On

the thirty-seventh postoperative day the arterial pressure was 98 systolic and 66 diastolic.

An appreciable diminution in the cyanosis of the lips and fingernails was apparent several days after operation. The patient was allowed to walk, beginning two and a half weeks after operation. This exercise resulted in a slight increase in the cyanosis, but it was evident that cyanosis was much less than it had been preoperatively. By the end of the third week she could walk 60 feet in an erect posture without panting, whereas before operation, stooping and leaning forward, she could walk only 30 feet and would then stop and pant. There has been a slow but steady recession of the clubbing of the fingers and toes. The patient was discharged from the hospital on the thirty-eighth postoperative day.

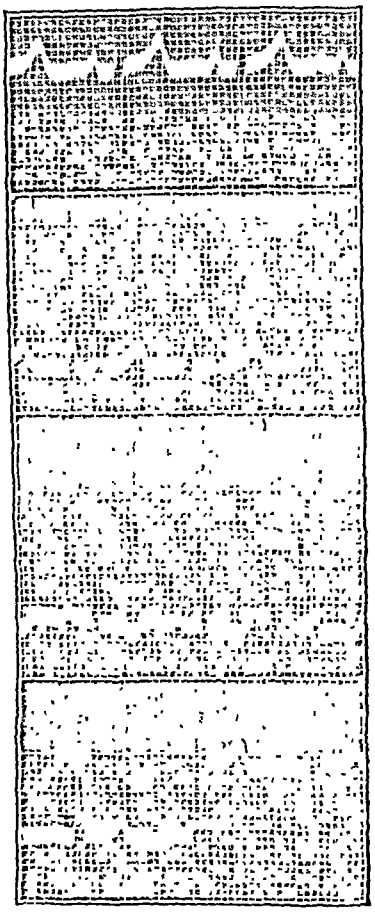

Fig. 7 (case 2).—Electrocardiogram.

CASE 3.—*History.*—M. M., a boy born July 15, 1938, was first seen at the Harriet Lane Home at 8 months of age with the complaint of heart trouble.

The family history is of importance in that the maternal grandfather was known to have heart trouble and had had a heart murmur throughout his life. The mother's brother and sister are both reported to have dextrocardia; both have refused examination.

The past history stated that the patient was a full term baby. The birth weight was 6½ pounds (2,955 Gm.). Development was slow; he held his head up at 5 months and sat alone at 6½ months. At 8 months the patient weighed 13½ pounds (6 Kg.). When lying quietly he showed slight persistent cyanosis, which became intense when he cried. On examination of the heart there was no thrill but a very definite systolic murmur, which was audible all over the precordium and well heard in the back. Fluoroscopy showed that the heart was within normal limits in size. There was a wide shadow above the heart which was interpreted as a large thymus. There was no fulness of the pulmonary conus, and the shadow at the base of the heart was concave. The clinical diagnosis was tetralogy of Fallot.

The patient was followed in the cardiac clinic until January 1940, when the family moved to California. They returned to Baltimore in the fall of 1944 and the patient was again brought to the clinic on September 29. At that time the boy, 6 years of age, was thin and undernourished, intensely cyanotic and dyspneic on slight exertion. The temperature was 99.2 F., weight 34½ pounds (15.6 Kg.), height 42 inches (107 cm.), pulse 140, respirations 20 and blood pressure 90 systolic and 60 diastolic.

There was manifest suffusion of the conjunctiva. The lips were purple and the buccal mucous membranes were a deep mulberry color. The teeth were in bad condition; the tonsils were not unduly enlarged. The chest was barrel shaped. The increase in the size of the heart was in proportion to the growth of the child. There was a systolic thrill at the apex and a harsh systolic murmur, which was maximal along the left sternal border in the third interspace. The second sound at the base of the heart was clear, but not accentuated. The lungs were clear. The liver was at the costal margin; the spleen was not palpable. The femoral arterial pulsations were easily felt. The extremities showed deep cyanosis and pronounced clubbing. Although the patient had learned to walk by November 1944, he was so incapacitated that he was unable to walk and even refused to try to take a few steps. The diagnosis was tetralogy of Fallot with a severe degree of pulmonary stenosis.

The patient was referred to the dental clinic, where several teeth were extracted. Sulfadiazine was given for two days. One month later the patient returned to the cardiac clinic with a rectal temperature of 100.4 F. and with numerous petechiae on his legs, which the mother said were of two days' duration. A blood culture taken at this time was sterile and no further petechiae appeared.

TABLE 2.—*Studies on Arterial Blood (Case 3)*

Dates	Arterial Oxygen Content, Volumes per Cent	Arterial Oxygen Capacity, Volumes per Cent	Arterial Oxygen Saturation, per Cent	Arterial Carbon Dioxide Content, Volumes per Cent	Comment
2/ 8/45	7.3	31.2	23.4	27.5	Patient struggling
2/ 9/45	10.7	30 2	35.5	29 3	Patient quiet
2/10/45	Innominate artery anastomosed to right pulmonary artery				
2/19/45	17.7	22.2	79.7	37.4	Patient crying
3/ 6/45	17.7	21.1	83.8	35.2	Patient quiet

The family was desirous of prompt operation and the patient was admitted to the hospital on Feb. 7, 1945. The results of analyses of blood obtained by arterial puncture are shown in table 2. With venous blood the red blood cell count was 10,000,000, the hemoglobin 26 Gm. and the hematocrit reading 81. The patient continued to have a daily elevation of temperature.

An electrocardiogram showed a normal sinus mechanism, a normal PR interval of 16, high *P* waves in L_2, and normal upright T waves in leads 1, 2 and 4, and T_3 inverted and an apparent right axis deviation.

X-ray examination (fig. 10) showed that the maximal right diameter of the heart was 2.1 cm., the maximal left 7 cm. and the total transverse diameter 18.8 cm.; the cardiothoracic ratio was 47.5. There was no fulness of the pulmonary conus. Fluoroscopy showed that the aorta descended on the left, and there were no visible pulsations in the lung fields.

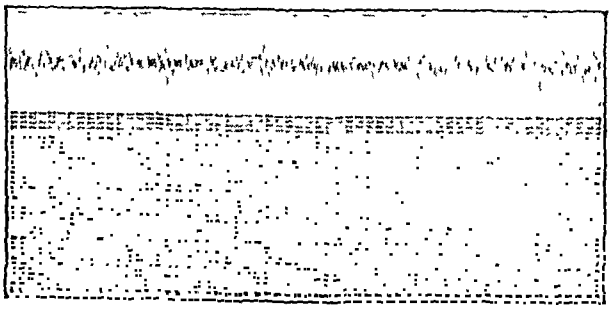

Fig. 8 (case 2).—Stethocardiogram.

Operation.—This was performed on February 10. The procedure consisted in anastomosing the divided proximal end of the innominate artery to the side of the right pulmonary artery. This is shown diagrammatically in figure 9. The anesthetic agent was administered by Dr. Merel Harmel.

Anesthesia was produced by cyclopropane with a high concentration of oxygen. It is of interest that the patient's color was much better under anesthesia than it had been previously.

This patient did not have a right aortic arch. In view of the great improvement in the second case we wished to use the innominate artery, and therefore the incision was made on the right side. There were no adhesions between the lung and the chest wall, and the lung appeared normal. The right upper lobe was retracted downward and the azygos vein was visualized. It was doubly ligated and divided. The superior vena cava and phrenic nerve were retracted medially, and the artery to the right upper lobe of the lung was seen. This was followed medially and the main right pulmonary artery was exposed. This exposure was considerably more difficult than that on the left side. Attention was then turned to the innominate artery. By dissecting under and medial to the superior vena cava the innominate artery was exposed and was dissected free of the surrounding tissues. This vessel was occluded temporarily by the use of a lung tourniquet which was equipped with a catheter overlying a piece of braided silk. The subclavian artery and the common carotid artery were ligated just distal to their origins from the innominate artery. The innominate artery was cut across proximal to these ligatures. Two bulldog clamps were placed on the right main pulmonary artery, and a transverse incision was made into the vessel between these clamps. The proximal bulldog clamp was not of sufficient length to secure entire control of the flow of blood. This resulted in a moderate loss of blood, and another clamp was substituted.

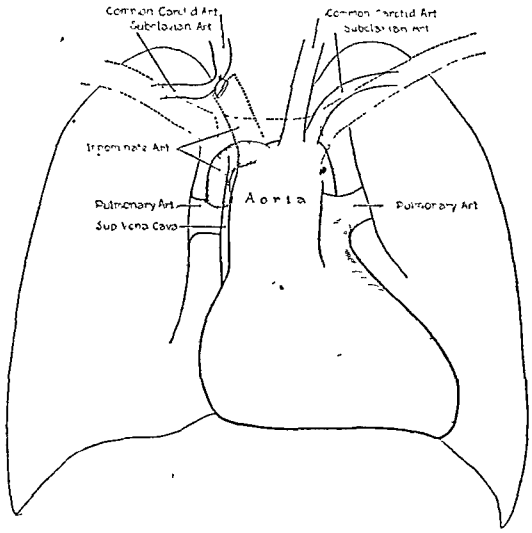

Fig. 9 (case 3).—Procedure used. The end of the innominate artery was anastomosed to the side of the right pulmonary artery.

With 5-0 silk on a small curved needle an anastomosis was made between the divided proximal end of the innominate artery and the side of the right main pulmonary artery. This anastomosis was more difficult than that in the previous cases because the exposure was less satisfactory. Following the removal of the bulldog clamps from the pulmonary artery there was a rather copious flow of blood from one point along the anterior row of sutures. The clamps were reapplied, and this opening was closed with a mattress suture. Subsequent removal of the clamps did not result in further bleeding. The patient's condition up to the time of this blood loss had been excellent. Occlusion of the right pulmonary artery had not seemed to increase the cyanosis. There was an increase in the cyanosis and a decline in pressure when this loss of blood occurred. It was estimated that at least 250 cc. of blood was lost.

The anastomosis seemed to be a satisfactory one. An easily palpable thrill could be felt in the pulmonary artery both proximal and distal to the anastomosis. It was estimated that the lumen of the innominate artery was slightly less than 1 centimeter in diameter. The right lung was partially inflated and the incision in the chest wall was closed.

The patient received 500 cc. of a mixture of isotonic solution of sodium chloride and glucose and 200 cc. of plasma during the operative procedure. The operation required a total of three hours, the greater part of this time being consumed in making the anastomosis. It was obvious that a better instrument for occluding the pulmonary artery proximal to the site of the anastomosis is needed. The right pulmonary artery was occluded for approximately ninety minutes.

The patient's condition at the completion of the operation was very good. He was conscious a few minutes after the incision had been closed, was asking for water and was moving his right arm. This arm was slightly cooler than the left. Pulsations could not be felt in the right arm or in the right side of the neck and the face. There was, however, no evidence of cerebral damage, and it was obvious that the circulation of the arm was adequate to maintain life.

Postoperative Course.—This was remarkably smooth. The patient was placed in an oxygen tent for several days. The circulation to the right arm remained adequate. Aspiration of the chest was not necessary. Immediately after operation the child's color improved. It was seen on the fourth postoperative day when the administration of oxygen was discontinued that the cyanosis of the lips had disappeared. The cyanosis of the fingertips decreased more slowly. The administration of penicillin was started the day before the operation and was continued for three weeks postoperatively. Dicumarol was given by mouth, beginning on the third postoperative day. The usual daily administration was 25 mg. Prothrombin determinations were performed daily, and the drug was continued for three weeks.

Although a thrill was palpable at the site of the anastomosis after the arterial clamps had been released, no murmur was audible immediately after the chest had been closed. By the first evening a faint murmur was audible, which gradually increased in intensity. By the fourth postoperative day a continuous murmur was audible over the site of the anastomosis and posteriorly throughout both lungs.

The child's compensation has remained excellent. In contrast to a preoperative arterial pressure of 85 systolic and 65 diastolic, the arterial pressure postoperatively was usually 106 systolic and 52 diastolic. The heart increased somewhat in size during the first ten days after operation, but there did not appear to be a further increase in the subsequent two weeks. Roentgenograms of the heart both before and after operation are shown in figure 10.

Arterial punctures were performed on the 9th and 24th postoperative days. The results of the analyses are given in table 2. On comparing the preoperative studies with those performed twenty-four days after operation, samples of venous blood showed that the red blood cell count decreased from 10,000,000 to 6,000,000, the hemoglobin from 26 to 20 Gm. and the hematocrit reading from 81 to 53 (Wintrobe).

The patient had had a preoperative daily elevation of temperature to 100 F., and this continued for three weeks after operation. For this reason he was not allowed out of bed despite his vigorous protests until three and a half weeks after operation. When permitted to do so, the child walked 40 feet with ease. He was then allowed to be up for several hours each day and has walked and played in his room. He did not develop either cyanosis or dyspnea on this activity. The patient was discharged from the hospital on the thirty-eighth postoperative day.

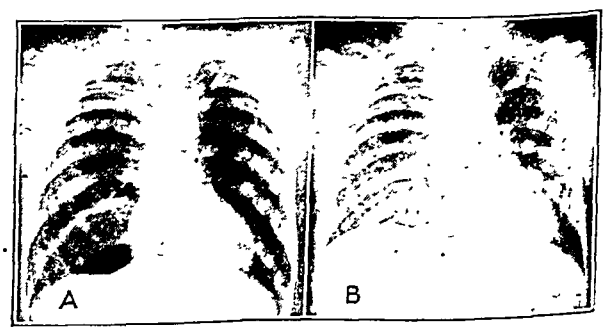

Fig. 10 (case 3).—Heart *A*, before operation and *B*, two weeks after operation.

COMMENT

Each of these 3 patients suffered from such a severe degree of pulmonary stenosis that there was inadequate circulation to the lungs. Although the three operations differed in detail, in each instance the operation greatly increased the volume of blood which reached the lungs.

In the first case the end of the left subclavian artery was anastomosed to the side of the left pulmonary artery. As the baby was small and weak, extensive laboratory studies were not performed. Before operation the baby had been steadily losing ground. She had ceased to be able to sit alone; she had refused her feedings and had lost weight. The red blood cell count had declined from 7,000,000 to 5,000,000; consequently the cyanosis had diminished considerably. After operation her clinical improvement was remarkable. The appetite improved, she gained weight and she is now starting to learn to walk.

The second patient had a right aortic arch; hence it was possible to anastomose the innominate artery to the left pulmonary artery. The patient was deeply cyanotic and severely incapacitated and could not walk 30 feet without panting. Two and a half weeks after operation she walked 60 feet, rested a short time and walked 60 feet back to her room and sat down quietly. The seriousness of her condition and the extent of the improvement are shown by the changes in the oxygen saturation of the arterial blood, which was 36.3 per cent before operation and which rose to 82.8 per cent three weeks subsequently. The red blood cell count dropped from 7,500,000 to 6,000,000, the hemoglobin from 24 Gm. to 17.5 Gm. and the hematocrit reading from 71 to 55.

The success of the second operation led us to perform the same operation in the third case Since the aorta was in the normal position, in order to use the innominate artery the operation was performed on the right side. The end of the innominate artery was anastomosed to the side of the right pulmonary artery. The patient was younger, and improvement was even more dramatic. Before operation he was intensely cyanotic, the lips were a dark purple, and the child was unable to take even a few steps. The day after operation he lay in an oxygen tent with cherry red lips. When taken out of the tent his color remained good. His disposition has changed from that of a miserable whining child to a happy smiling boy. We were slow to permit him to walk because of a persistent low grade fever, but at the end of the third postoperative week he could walk 40 feet without panting and without becoming cyanotic. The oxygen saturation of the arterial blood rose from 35.5 to 79.7 per cent in nine days, and it reached a saturation of 83.8 per cent twenty-four days after operation. The red blood cell count fell from 10,000,000 to 6,000,000; the hemoglobin decreased from 26 Gm. to 20 Gm. and the hematocrit reading from 81 to 53.

There are a number of features of the operative procedure which merit discussion. We were fearful that an intensely cyanotic child would not tolerate a long operative procedure in which it was necessary to open the pleural cavity and to occlude temporarily one of the pulmonary arteries. For this reason our first clinical attempt to increase the circulation to the lungs was postponed almost a year after it was decided that the procedure was a sound one, with the hope that some method of administering oxygen in addition to inhalation might prove satisfactory. This seemed particularly important since it was obvious that a new and untried procedure should be performed first on patients with a severe degree of anoxemia whose outlook without aid of some sort was hopeless. Although the use of intravenous oxygen has been reported by Ziegler [12] and may prove to be of benefit in this operation, it was impossible during wartime to procure the necessary equipment. Therefore this method could not be studied.

From our limited experience it appears that this type of patient can tolerate the use of inhalation agents for general anesthesia. We have been fortunate in this respect in that the anesthetic agents were chosen and administered expertly by Dr. Austin Lamont and Dr. Merel Harmel.[13] The first of these 3 patients was only 14 months of age and weighed less than 9 pounds. Ether by the open drip method was used during the major part of the procedure for the reason that a sufficiently small closed system was not available. In the anesthetization of the second and third patients, cyclopropane with a high concentration of oxygen was employed. Fortunately the administration of oxygen apparently increased the oxygen content of the arterial blood and cyanosis was definitely lessened. Although in only 1 patient was there any serious hemorrhage, the precaution was taken of having both blood and plasma readily available. Indeed, a slow continuous drip of plasma is advisable so that at a moment's notice if necessary the patient can be given large quantities of plasma. With these precautions no great difficulty was encountered in spite of the fact that two of the three operations required three hours.

The next question which arose was whether a patient who was already suffering from a severe degree of anoxemia would tolerate the occlusion of one of the main pulmonary arteries for the period during which the anastomosis was being performed. These periods of occlusion were approximately thirty, sixty and ninety minutes in the three operations. It is a remarkable fact that the cyanosis did not appear to be greatly increased during the occlusion period. It may be that the decreased flow of blood to the lungs caused by the congenital deformity rendered it possible for the opposite artery and lung to utilize this reduced volume almost as effectively as could the two lungs. Be that as it may, the 3 children tolerated occlusion of the left or the right main pulmonary artery for periods ranging from approximately thirty to ninety minutes.

Another question which arose was whether ligation and division of the left subclavian artery or the innominate artery would result in serious impairment of the circulation to the arm and the brain. In most instances heretofore these vessels have been occluded because of preexisting disease such as aneurysm, and it is possible under such circumstances that there has been a prolonged stimulus for the formation of collateral arterial pathways. It was gratifying, therefore, to note in our patients that there was little evidence of impairment of circulation to the parts deprived of their major arterial pathway. It is true that the pulse was absent for some time postoperatively and the part was slightly cooler than that of the opposite part of the body, but immediately after operation it was evident that the circulation was adequate to maintain life of the part. It may prove desirable to perform an upper dorsal sympathectomy at the time of operation. This would not add to the gravity of the operative procedure, since one has an excellent exposure of this region in perform-

13. Drs. Lamont and Harmel will deal with this subject in a subsequent communication

ing the arterial anastomosis. In future cases the circulation of the arm will be studied more carefully.

The operation has not been attempted before on patients and there are many operative as well as clinical features which are still under investigation. The first of these is concerned with the type of anastomosis which is to be performed. This will undoubtedly depend on many factors, especially the age of the patient and the degree of anoxemia. As stated previously, in our patients the anastomosis was performed between the end of the subclavian artery or innominate artery and the side of the left or right pulmonary artery. This type of anastomosis appears to be sound in that it allows the blood to flow from the systemic circulation to both lungs. The fact that the continuous murmur which results from the operation is readily audible on both sides of the chest indicates that the anastomosis does direct blood to both lungs. It was this type of anastomosis which was used by Eppinger, Burwell and Gross [8] in their studies on the cardiac output of dogs with an artificial ductus arteriosus.

The easiest of the end to side arterial anastomoses in this region is that between the end of the left subclavian artery and the side of the left pulmonary artery. On the other hand, the subclavian artery is so small in an infant that the chances of the occurrence of thrombosis at the anastomotic site are great. This is particularly true if the patient has extreme polycythemia. Even though the anastomosis remains patent, the size of the vessel is a limiting factor in the flow of blood to the lungs which may not be sufficient to overcome the high degree of anoxemia from which some of these patients suffer. In an older patient with only a moderate degree of cyanosis the subclavian artery would appear to be the ideal vessel. The left common carotid is somewhat larger than the left subclavian artery, and its employment under some circumstances seems to be warranted. When dealing with the degree of anoxemia which was present in our patients, the innominate artery is much to be preferred to the left subclavian artery or the left common carotid artery. The performance of the anastomosis is not very difficult when the left pulmonary artery can be used. The anastomosis of the innominate artery to the left pulmonary artery is possible only in patients with a right aortic arch and hence an innominate artery on the left. With the innominate artery in its normal position the anastomosis of this vessel to the right pulmonary artery is more difficult because so much of the latter artery lies behind the aorta and the superior vena cava. Improvements in the designs of instruments will facilitate this procedure.

It is important to bear in mind that the degree of impairment in the flow of blood to the lungs varies from patient to patient, and the selection of the vessel to be used depends on the extent of the need of the patient for an increase in the circulation to the lungs. Experimental observations and clinical trial and error will undoubtedly shed additional light on this subject. It is obvious that the vessel chosen and the size of the anastomosis itself should not be larger than is necessary for the relief of anoxemia because of the danger associated with excessive shunting of blood to the lungs.

There are other methods in addition to union of an end of a systemic artery to the side of a pulmonary artery by which an anastomosis between the two circulations may be made. Included among these are (1) anastomosis of the divided proximal end of one of the vessels which arise from the aortic arch (innominate, left common carotid, left subclavian) to the divided distal end of one of the two pulmonary arteries, (2) anastomosis of the divided proximal end of the subclavian artery or the common carotid artery to the divided proximal end of the pulmonary artery to an upper lobe of one of the lungs, (3) anastomosis of the side of the aorta to the side of the left pulmonary artery and (4) anastomosis of the side of the aorta to the side of the left pulmonary artery. These will be considered in the order in which they are enumerated.

The results of the use of the first method, in which the divided proximal end of the left subclavian artery is anastomosed to the divided distal end of the left main pulmonary artery, were reported in 1939 by Levy and Blalock.[7] It was stated that "dogs which have been observed for several months following this procedure appear entirely normal. The left lung was aerated and the respiratory movements were unaltered. The systemic arterial blood pressure was not affected by this operation. The blood pressure in the pulmonary artery only a short distance beyond the anastomosis was less than half of that in the systemic arteries. This was due to the relatively low peripheral resistance in the pulmonary bed. Since only arterial blood entered the left lung, the quantity of oxygen consumed by this lung was very small. However, when anoxemia was caused, a larger quantity of oxygen was taken up by the incompletely oxygenated arterial blood. The left lung appeared pinker than the right on gross examination during life. Microscopic examination revealed no noteworthy alteration in either the left pulmonary artery or lung." Some of these animals have now been observed over periods ranging up to six years. The only disturbing finding has been that a few of the animals at autopsy have shown a thickening of the left pulmonary artery. It was noted by Dr. Arnold Rich that this was found only in instances in which the anastomotic site was partially occluded as a result of thrombosis. The discrepancy in the size of the left subclavian artery and that of the left pulmonary artery may have accounted in part for this finding. Furthermore, this discrepancy in size may be responsible in part for the sudden diminution in the arterial pressure just beyond the point of anastomosis. At any rate, it is improbable that the anastomosis of the subclavian artery to the end of the left pulmonary artery would be the procedure of choice in the treatment of pulmonic stenosis. If this type of anastomosis should be performed, the innominate artery would be a better choice than the subclavian because it is more nearly the size of the pulmonary artery. It may be found that an end to end anastomosis is more apt to remain patent than an end to side one; certainly it is technically easier to perform. If, in the process of performing an anastomosis between the end of the innominate artery and the side of one of the pulmonary arteries, the latter vessel should be torn beyond repair, it should be borne in mind that an anastomosis may still be performed between the end of the innominate and the distal end of the pulmonary artery. Experimental studies are being carried out on the relative virtues of end to end and end to side anastomoses.

A second alternative method consists in anastomosing the proximal end of the divided subclavian or carotid artery to the proximal end of the divided pulmonary artery to one of the upper lobes. Since it is technically easier to perform an end to end than an end to side anastomosis, one may consider the advisability of using

this procedure for a patient with only a slight degree of cyanosis. The proximal end of the pulmonary artery is specified because this would conceivably allow blood to gain access to all the lobes except the one supplied by the artery which was used for the anastomosis. This procedure has been performed in the laboratory and is not difficult.

The third possible operative procedure is concerned with an anastomosis of the side of the aorta to the side of the left pulmonary artery. That such a procedure is possible in dogs has been shown by Leeds [9] in his studies on patent ductus arteriosus. We considered the use of this method in our patients but were discouraged by the experience of Blalock and Park [10] in studies on experimental coarctation of the aorta. In these experiments the aorta was divided just distal to the ligamentum arteriosum, the two ends of the aorta were closed, the left subclavian artery was divided at some distance from the arch of the aorta, and the proximal end of the divided subclavian artery was anastomosed to the side of the distal end of the aorta just below the point at which it had been divided. Thus the subclavian artery was used for the conduction of blood beyond the point of division of the aorta. The discouraging feature of these experiments was that in approximately half of the animals the hind legs were paralyzed at the completion of the operative procedure. In 1 dog in which we occluded the aorta for forty minutes for the purpose of making an anastomosis between the side of the aorta and the side of the left pulmonary artery the hind legs became paralyzed. It is impossible to make an accurate anastomosis between the aorta and the left pulmonary artery without interrupting temporarily the circulation through the two vessels. We were fearful of causing a paralysis of the lower extremities and hence did not use this method with our patients. Another difficulty associated with the use of the aorta is that its walls are thick and rather friable and it is difficult to obtain an accurate approximation of the intimal surfaces.

The fourth method to be considered is that of an anastomosis of the aorta and the main pulmonary artery. It is obvious that occlusion of these vessels for the length of time that is required for an open suture anastomosis would result in death. If such a union was to be secured, it would have to be done by some other method. Fortunately the first portions of the medial walls of the aorta and the pulmonary artery are intimately adherent to each other. The ascending aorta and the main pulmonary artery are contained within the pericardial cavity and are enclosed in a tube of serous pericardium common to the two vessels. We have been able to produce a fistula between the two vessels in dogs by inflicting a stab wound in this region. The knife blade was introduced through the opposite free wall of the pulmonary artery, the walls of the pulmonary artery and aorta which were in intimate contact were pierced, the knife was withdrawn, and the opening in the free side of the pulmonary artery was closed by sutures. The establishment of the fistula required only a few seconds. This method is mentioned because it may be necessary to use the major blood vessels and to employ considerable speed if newborn infants with pulmonary stenosis or atresia are to be saved. It would not be at all surprising if this experimental method should prove to be a useful one in patients.

It remains to be proved whether a communication between the two circulations should be brought about by direct anastomoses between blood vessels such as we have employed or by the use of tubes such as those devised for other purposes by Blakemore, Lord and Stefko.[14] It is our impression that the suture method is preferable when it can be accomplished without undue tension. This method obviates the necessity for leaving a large foreign body in the tissues; furthermore, there is at least a possibility that the opening will increase in size with the growth of the child. Studies on the latter point are in progress. These comments are in no sense a criticism of the Blakemore method, which is of great value in those instances in which part of a blood vessel has been destroyed and the ends cannot be united by direct suture.

One of the possible complications which causes concern is the danger of thrombosis at the anastomotic site. The improvement of our 3 patients indicates that thrombosis has not occurred. Furthermore, in cases 2 and 3 loud continuous murmurs developed after operation. As mentioned previously, partial occlusion of the anastomotic site has been found in some of the dogs in which such anastomoses were performed. Partial occlusion of the opening and emboli in the lungs were found at autopsy in 1 animal in which the end of the subclavian artery had been anastomosed to the side of the left pulmonary artery. This experiment was complicated by the previous creation of bilateral pulmonary arteriovenous fistulas. The sizes of the vessels used and the size of the communication between the two vessels are, of course, of prime importance in the determination of whether or not the opening will remain patent. This consideration is another point in favor of using a large vessel such as the innominate artery. Because of the difference in pressure on the two sides of the anastomotic site between the systemic and pulmonary circulations, it would be more likely that such an anastomosis would remain open than communications of similar size between two systemic arteries or two systemic veins.

As previously stated, most patients with the type of malformation of the heart under consideration have a decided polycythemia and an increased viscosity of the blood. This condition undoubtedly increases the danger of thrombosis. Indeed, cerebral thromboses are of not infrequent occurrence in these patients. Therefore the question arose as to whether these patients should receive heparin shortly after the termination of the operation. After much deliberation it was decided that the possible dangers were greater than the possible advantages. This opinion, however, is subject to change. By way of compromise, it was decided to give dicumarol during the period of convalescence. Therefore, beginning respectively on the fourth and third postoperative days the second and third patients were given dicumarol in small quantities. Prothrombin determinations were made daily and the dose of dicumarol was regulated so as to keep the clotting time approximately double that of the normal control. This medication was continued for a period of approximately three weeks. It is impossible to state whether this therapy has been of importance in the maintenance of the patency of the fistulas.

In order to understand the changes produced by the operation and its application to other malformations, it is essential to understand the nature of this malformation and the course of the circulation. The four features which constitute the tetralogy of Fallot are pulmonary stenosis, dextroposition of the aorta, an inter-

14. Blakemore, A. H.; Lord, J. W., Jr., and Stefko, P. L.: Restoration of Blood Flow in Damaged Arteries: Further Studies on Nonsuture Method of Blood Vessel Anastomosis, Ann. Surg. 117: 481-497, 1943.

ventricular septal defect and right ventricular hypertrophy. The pulmonary stenosis consists in a narrowing of the pulmonary orifice, and it is usual to find that the constriction also involves the pulmonary conus of the right ventricle. Dextroposition of the aorta means that the aorta rises from the left ventricle and partially overrides the right ventricle. Whenever this occurs, the aortic septum cannot meet the ventricular septum; consequently there is a high ventricular septal defect. Such is the nature of an interventricular septal defect in the tetralogy of Fallot. The malformation renders it difficult for the blood to be expelled from the right ventricle; hence there is hypertrophy of that chamber. The structure of the heart and the course of the circulation are diagrammatically shown in figure 11.

The degree of incapacity in a tetralogy of Fallot depends on the severity of the pulmonary stenosis and the degree of the overriding of the aorta. It is well known in cases in which the pulmonary stenosis is not extreme that the malformation is compatible with relative longevity. However, with extreme degrees of pulmonary stenosis and greatly diminished circulation to the lungs, the condition causes severe incapacity and death occurs at an early age.

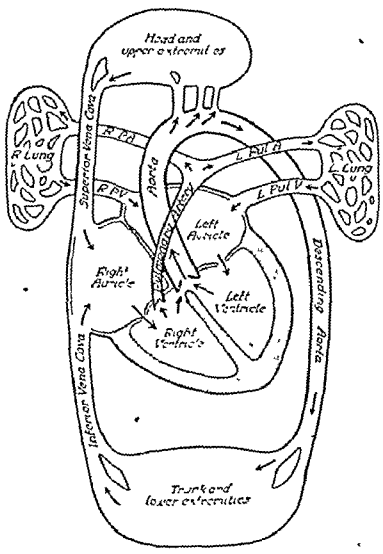

Fig. 11. Diagram of the course of the circulation in the tetralogy of Fallot. In this malformation there is pulmonary stenosis, the aorta is dextroposed and hence receives blood from both ventricles, the ductus arteriosus undergoes normal obliteration and the foramen ovale is closed. The blood from the right auricle flows into the right ventricle; hence part of the blood is pumped through the stenosed pulmonary orifice into the pulmonary artery and part of the blood is pumped directly into the aorta. Only that portion of the blood from the right ventricle which is pumped into the pulmonary artery goes to the lungs for aeration and is returned to the left auricle and the left ventricle. All of the blood from the left ventricle and some of the blood from the right ventricle is pumped out into the aorta to the systemic circulation and is returned by the superior vena cava and the inferior vena cava to the right auricle. There the cycle starts again.

The anastomosis of the innominate artery to the pulmonary artery directs a large volume of blood from the systemic circulation into the pulmonary circulation. By this means the volume of blood which reaches the lungs for aeration is increased; it follows that a greater volume of oxygenated blood is returned by the pulmonary veins to the left auricle and the left ventricle; consequently a greater volume of oxygenated blood is pumped out into the systemic circulation. As some blood from the aorta is diverted to the pulmonary circulation, the volume of blood to the systemic circulation is decreased and less blood is returned to the right auricle and the right ventricle. Thus the volume of blood which is returned to the right ventricle is lessened and that which is returned to the left side of the heart is increased. The alteration in the course of the circulation as influenced by the operation is shown in figure. 12.

In short, the operation enables some blood to bypass the obstruction to the pulmonary circulation. Hence the operation should be of value in all malformations in which the primary difficulty is due to lack of adequate circulation of the blood to the lungs; that is, in all cases of the tetralogy of Fallot and complete pulmonary atresia, in cases in which the right ventricle is absent or defective in its development, in cases of truncus arteriosus with bronchial arteries, or even a single ventricle with a rudimentary outlet chamber in which the pulmonary artery is diminutive in size.

Complete pulmonary atresia is, of course, compatible with life only as long as the ductus arteriosus remains open unless the bronchial arteries dilate and establish sufficient collateral circulation for the maintenance of life. This, we believe, happened in case 2, as at operation large aberrant vessels were found in the region of the hilus of the left lung. However, in the great majority of cases of pulmonary atresia the closure of the ductus arteriosus is so rapid that adequate collateral circulation does not develop and consequently the condition is fatal in early infancy. In all such cases the operation, if performed early, may be life saving. The same is true in cases of a defective development of the right ventricle in which all of the blood from the right auricle is directed to the left auricle and hence to the left ventricle and out by way of the aorta, and the only circulation to the lungs is by way of the ductus arteriosus.[15] The operation should be equally valuable in cases of truncus arteriosus with bronchial arteries because the bronchial arteries never become sufficiently large to provide adequate circulation to the lungs.

In every instance there is, of course, an admixture of venous and arterial blood. It would be impossible, therefore, to bring the oxygen saturation of the arterial blood to normal; nevertheless, it is conceivably possible to bring the oxygen saturation of the arterial blood sufficiently high so that there would be no "visible" cyanosis. Certainly in the 2 older children there has been an increase in the oxygen content of the arterial blood, a decrease in the oxygen capacity, an increase in the oxygen saturation of the arterial blood, a decrease in the red blood cell count, a diminution in the hemoglobin and the hematocrit reading, a striking decrease in the patients' disability and a great improvement in the patients' ability to exercise.

In cases of the tetralogy of Fallot the heart is either normal in size or relatively small. Following the creation of an artificial ductus, the increased volume of blood which reaches the pulmonary circulation undoubtedly increases the work of the left side of the heart. In our patients the heart has definitely increased in size but compensation thus far has remained excellent. Sir Thomas Lewis[16] has emphasized that in cases of coarctation of the aorta prolonged overwork does not cause cardiac failure. Palmer[17] in his studies on cardiac enlargement showed that, in essential hypertension, cardiac enlargement occurs with the gradual rise in blood pressure and that progressive enlargement does not easily occur after the blood pressure level has become stabilized. Therefore it is our hope and expectation that in this operation, although the heart immediately increases in size in response to the altered blood flow, the condition will not lead to progressive cardiac enlargement. It is encouraging that in both cases 2 and 3, although the heart increased in size in the first ten days, there was no further increase in the second ten days.

It is important to emphasize that the operation is not of value to all patients with persistent cyanosis. It is of value only in malformations in which the primary difficulty is lack of circulation to the lungs. The operation would be of no use in cases of complete transposition of the great vessels or in the so-called "tetralogy of Fallot of the Eisenmenger type" and probably not in aortic atresia.

In complete transposition of the great vessels the pulmonary artery arises from the left ventricle and the aorta from the right ventricle. The blood from the left ventricle is pumped out through the pulmonary artery to the lungs and is returned by the pulmonary veins to the left auricle and thence to the left ventricle. The blood from the right side of the heart is pumped out into the aorta to the systemic circulation and is returned by the superior vena cava and the inferior vena cava to the right auricle and the right ventricle. The primary difficulty in this malformation is not in the volume of blood which reaches the lungs but in the mechanism by which the blood which has been oxygenated in the lungs can reach the systemic circulation.

In the Eisenmenger complex cyanosis appears to be due to secondary changes in the alveolar wall or in the pulmonary vascular bed of such a nature as to hinder the aeration of the blood as it passes through the lungs; it is even possible that the high pressure in the lesser circulation may increase the right to left shunt and thereby increase the volume of reduced hemoglobin in the arterial blood. In any event, in this malformation there is no lack of circulation to the lungs and, furthermore, only rarely, if ever, is there deep cyanosis in early childhood.

In aortic atresia[18] not only is there difficulty in pumping blood to the systemic circulation but also the blood which does reach the systemic circulation is pumped through the ductus arteriosus before it has been to the lungs for aeration. Under such circumstances the creation of an additional ductus arteriosus would act to direct a larger volume of blood to the body; but it must be borne in mind that this blood has the same oxygen content as that directed to the lungs.

It is worthy of note in almost all patients with much polycythemia that all of the blood which circulates through the lungs is no longer fully oxygenated. Whether the size of the capillary bed in the lungs varies with the plasma volume and not with the number of red blood cells is not known, but there is clear evidence to show that even in patients in whom the primary difficulty is lack of circulation to the lungs the oxygen saturation of the arterial blood can be appreciably raised by the prolonged inhalation of a high concentration of oxygen. The potency of this factor was demonstrated by the great improvement in the peripheral cyanosis during operation when the patients were receiving oxygen. The importance of the volume of blood which reaches the lungs for aeration is demonstrated in our patients by the extent of the rise in the oxygen saturation of the arterial blood which resulted from the operation; in 1 instance it rose from 36 3 to 82 8 per cent and in the other from 35.5 to 83 8 per cent.

It may be that, with prolonged meager flow of blood to the lungs, secondary changes occur so that the pulmonary capillary bed is no longer capable of complete expansion and restoration to normal Our 6 year old child showed prompter improvement than did the 12 year old girl. Hence the operation may prove less beneficial to older persons than to young children. For this reason the ideal age for operation appears to be after the systemic pressure has risen sufficiently high to permit the continuous flow of blood from the aorta to the pulmonary artery and before the condition has persisted long enough to cause irreversible changes in the lungs. We believe that the optimal age of patients is probably between 4 and 6 years, however, in all cases in which the closure of the ductus arteriosus renders the malformation incompatible with life the operation must be performed in early infancy.

Since the operation should be of value to all patients in whom the primary difficulty is lack of circulation to the lungs, it behooves the clinician to recognize this condition.[19] The two outstanding features, both of which should be present, are (1) roentgenographic evidence that the pulmonary artery is diminutive in size and (2) clinical and roentgenographic evidence of absence of congestion in the lung fields.

The size of the normal pulmonary artery is not difficult to determine by roentgenography. The striking feature in the roentgenogram is the absence of the fulness of the normal pulmonary conus. The shadow at the base of the heart to the left of the sternum is concave and not convex. A concave shadow in this region in patients with persistent cyanosis always means that the pulmonary artery is misplaced, absent or diminutive in size.[2] When the pulmonary artery is absent or diminutive in size, there is the additional finding in the left anterior oblique position of an abnormally clear pulmonary window.[2]

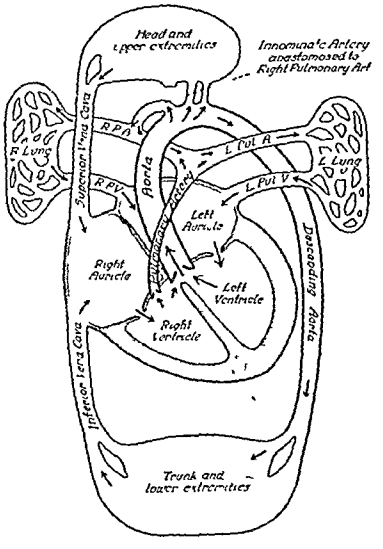

FIG. 12.—Diagram of the course of the circulation in the tetralogy of Fallot after the anastomosis of the innominate artery to the pulmonary artery. Under these circumstances the blood from the right auricle flows into the right ventricle and, as before, part of the blood from the right ventricle is pumped directly into the aorta Now, in addition to the blood which is pumped through the pulmonary orifice into the pulmonary artery, some of the blood from the aorta is diverted through the anastomosis to the lungs Thus the volume of blood which reaches the lungs is increased and the volume of oxygenated blood which is returned to the left auricle and the left ventricle is proportionately increased. All of the blood from the left ventricle and also some blood from the right ventricle is pumped into the aorta Some of the blood from the aorta is directed to the lungs, and the remainder goes to the systemic circulation and is returned by the superior vena cava and the inferior vena cava to the right auricle Thus the left ventricle receives more blood than before operation and the right side of the heart receives less The operation has bypassed the obstruction in the circulation of the blood to the lungs

Absence of clinical and x-ray evidence of congestion in the lungs is highly important in reaching a decision. When circulation to the lungs is inadequate, the diminished blood flow to the lungs lessens the chances of congestion in the lungs and congestion rarely occurs.[2] When congestion does occur, it suggests that the circulation to the lungs is adequate or excessive. The operation should never be attempted when x-ray exam-

18 Taussig, H. B.: Clinical and Pathological Findings in Aortic Atresia or Marked Hypoplasia of the Aorta at Its Base, Bull Johns-Hopkins Hospital, to be published

19 The following discussion is based mainly on original unreported observations which are dealt with in detail in chapters II and III of Taussig's forthcoming book on "The Clinical Analysis of Congenital Malformations of the Heart," to be published by the Commonwealth Fund.

ination shows a prominent pulmonary conus or when there are pulsations at the hili of the lungs. These pulsations should be looked for by careful fluoroscopic examination after one's eyes are fully accommodated.

Virtually the only malformation in which there is absence of the normal shadow cast by the pulmonary artery in the presence of adequate circulation to the lungs is complete transposition of the great vessels. In this condition the pulmonary artery lies behind the aorta; therefore, in the anteroposterior view there is a narrow aortic shadow and a concave curve at the base of the heart to the left of the sternum. In the left anterior oblique position the two vessels lie side by side; hence the shadow cast by the great vessels increases in width [20] and the pulmonary window is not abnormally clear. The condition does not cause pulsation at the hili of the lungs but frequently leads to congestion in the lung fields. These observations, together with evidence of relatively rapid progressive cardiac enlargement,[2] should aid in the establishment of the correct diagnosis.

The operation should be performed on the right or left side, depending on which vessel is to be used and on which side the aorta descends. Furthermore, it is important to bear in mind that the occurrence of a right aortic arch is by no means rare in congenital malformations of the heart which cause persistent cyanosis. Bedford and Parkinson [21] have shown that the determination of the course of the aorta is not difficult, provided fluoroscopy is carefully performed and the esophagus delineated with a barium opaque mixture. Normally the aortic knob is visible on the left, the esophagus lies in the midline and is indented by the aorta on the left margin, and in the right anterior oblique position the esophagus is seen to be slightly displaced backward by the aorta. In cases of a right aortic arch the aortic knob frequently is hidden within the shadow cast by the superior vena cava. In the anteroposterior view the esophagus is indented on the right and is displaced backward in the left anterior oblique position.

It remains to be seen whether these patients will develop heart failure. Even if this occurs, the intervening period appears to be one of great clinical improvement. It may well be that, if more patients with congenital malformations of the heart survive, more will develop subacute bacterial endocarditis. Certain it is that there is nothing in persistent cyanosis which renders an individual immune from subacute bacterial endocarditis. The condition is less frequently encountered in cyanotic persons only because a comparatively small number of patients survive long enough to be liable to contract the disease. The fear of subacute bacterial endocarditis in the future is no justification for allowing a patient to die of anoxemia in the present. Even the possibility of future cardiac failure does not weigh heavily against present extreme incapacity and the danger of early death from anoxemia or cerebral thrombosis.

SUMMARY

An operation for increasing the flow of blood through the lungs and thereby reducing the cyanosis in patients with congenital malformations of the heart consists in making an anastomosis between a branch of the aorta and one of the pulmonary arteries; in other words, the creation of an artificial ductus arteriosus. Thus far the procedure has been carried out on only 3 children, each of whom had a severe degree of anoxemia. Clinical evidence of improvement has been striking and includes a pronounced decrease in the intensity of the cyanosis, a decrease in dyspnea and an increase in tolerance to exercise. In the 2 cases in which such laboratory studies were performed there has been a decline in the red blood cell count, in the hemoglobin and in the hematocrit reading, an increase in the oxygen content of the arterial blood, a fall in the oxygen capacity, and most significantly a decided rise in the oxygen saturation of the arterial blood.

The types of abnormalities which should be benefited by this operation are the tetralogy of Fallot, pulmonary atresia with or without dextroposition of the aorta and with or without defective development of the right ventricle, a truncus arteriosus with bronchial arteries, and a single ventricle with a rudimentary outlet chamber in which the pulmonary artery is diminutive in size. The operation is indicated only when there is clinical and radiologic evidence of a decrease in the pulmonary blood flow. The operation is not indicated in cases of complete transposition of the great vessels or in the so-called "tetralogy of Fallot of the Eisenmenger type," and probably not in aortic atresia. It must be emphasized that the operation should not be performed when studies reveal a prominent pulmonary conus or pulsations at the hili of the lungs.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following article. HOWARD A. CARTER, *Secretary.*

THERAPEUTIC AND REMEDIAL EXERCISES

FRANK H. EWERHARDT, M.D.
ST. LOUIS

It is my purpose to confine myself to the practical application of physical exercise as related to the health of the human body rather than to discuss problems involved in the physiology of exercise.[1]

Almost all of the bodily movements done by a normal person throughout the day's routine, such as sitting, walking, eating and dressing, consist essentially of a successive recurrence of simple reflex acts. However, the matter of learning new movements has an entirely different significance and involves a review of the phenomenon of muscular control. It is interesting to syllogize on the subject of what happens when a boy learns to swim, a girl to knit or an athlete to pole vault. The answer is found in an understanding of the classification, action and coordination of muscles.

Skeletal muscles are classified as prime movers (protagonists or agonists), antagonists and synergists or fixers.

1. For studies on the physiology of exercise the reader is referred to Lipovetz (Applied Physiology of Exercise, Minneapolis, Burgess Publishing Company), who concisely interprets studies on the phenomenon of muscle contractions; the chemical changes of contraction; the phenomenon of muscular action, control and movement; equilibrium, postural tonus and tonus reflexes; nerve mechanism of the heart; innervation and chemistry of respiration, and the localization of brain function and the process of learning.

Prime movers (protagonists, agonists) are the muscles which actually produce an intended movement. The antagonists are those which tend to oppose the action of the prime movers. The synergists so modify the action of the first two that the intended movement is performed smoothly, free from shocks or jolts and with the least expenditure of energy. Without collaboration of these various groups the apparently simple act of bringing a glass of water to the mouth would indeed be awkward and conceivably impossible, much as the infant finds it difficult to convey a spoonful of food into his mouth.

Still another motivating force which contributes smoothness and grace in the process of performing an active exercise is the process of relaxation. Whenever a group of muscles contract normally, the respective antagonists are made to relax at the same time. Thus, when the elbow flexors are made to contract, causing flexion of the elbow, the movement is accompanied by a relaxation of the normal muscle tone of the extensors. This is a positive and not a negative action, known as Sherrington's law of reciprocal innervation.

Muscular activity falls into two main divisions, active and passive. The raising of a patient's arm in abduction is an active movement if performed by the sole efforts of the patient himself; it is a passive movement if applied by the assistant to the patient without the latter offering any assistance or resistance. The active group is further subdivided into various minor groups.

Active, voluntary purposeful movements are initiated by mental processes. They affect the upper and lower neurons, the motor and sensory nerves, the myoneural junction and the muscle itself. Neither passive movements nor muscular action initiated by an electrical impulse can so exclusively and favorably influence the neuromuscular arc. This intricate mechanism is so complete that when the command for movement is given by the brain cells there is always a clear mental picture of the intended movement. For a movement impulse to express itself, it must be controlled by the sensory nerves, for the will and the sensibility are functions inseparably connected with each other. Because of this intimate relationship between brain and muscle, voluntary purposeful movements are of vital importance in restoring various nerve-muscle disturbances to normal.

Occupational therapy permits and may augment active exercise. Skills and crafts can be taught and learned by the use of hands and legs. In this manner function can be more quickly restored by the patient continually repeating the desired active movements. By this means the monotony of a routine gymnastic exercise is avoided by appealing to the creative instinct of the patient. Patients with little or no interest in life may be stimulated frequently to an entirely different outlook by this form of active exercise.

Passive movements are performed by an operator without the assistance or resistance of the patient. This action must not be confused with manipulation of a joint limited in motion due to fibrous adhesions of extracapsular or intracapsular origin. Neither should it be recognized as a synonym for the term relaxing movements, since passive movements are in no way concerned in releasing tension of muscular tissue. Passive is a descriptive term meaning the opposite of active. In passive movements the sensory association motor neuron synapse is in no way involved, whereas this unit is definitely and vitally concerned in the phenomenon of relaxation.

The significance of passive movement will be more fully appreciated by noting its practical application in physical medicine:

(*a*) To be used preliminary to active movement when the latter may be harmful; i. e., in the treatment of fractures or when active movements may be harmful or actually impossible.

(*b*) To improve the return lymph and blood circulation by virtue of compression and joint motion.

(*c*) To retain full amplitude of joint motion by the prevention of contractures, shortening of muscles and the formation of adhesions.

(*d*) To maintain conscious proprioception.

(*e*) To maintain nerve power by stimulation through stretching and shortening of muscles.

Resistive movements are those in the course of which the technician resists the efforts of the patient, or vice versa. The technician offers just as much resistance as the patient is able to overcome. In certain pathologic conditions these movements have distinct advantages over the active voluntary type of exercise.

(*a*) Single muscles or groups of muscles can be caused to function to an optimal degree because of a more complete relaxation of the prime movers and a consequent lessened resistance. This phenomenon is due to the operation of Sherrington's law of reciprocal innervation. The technician resists to a degree permitting the greatest range of motion [page 26 (*a*) resistive movements].

(*b*) By the same token protective spasm may be lessened. For example, resistance to knee flexion relaxes the overactive quadriceps.

(*c*) The work done by the muscles can be graduated to any amount desirable.

(*d*) By virtue of *a* and *c* resistive movements offer an excellent method of studying muscular action and relative strength.

Assistive movements, as the name implies, are useful in supplementing voluntary effort where normal muscle power is deficient. For example, a patient with a weak deltoid in the supine position is asked to bring the arm to a 90 degree abduction.

During the range of motion, assistance is offered by the technician for the first and third part of the movement while the patient alone performs during the second part.

Isometric muscular contraction currently has been unsatisfactorily termed "muscle setting." The muscle is contracted but does not involve joint action. It is admirably adapted to conditions of fracture or joint injury to arm or leg. Though the patient's leg may be encased in a plaster cast, still he is able to carry on muscular contractions, thus improving the circulation and the muscle tone.

AIDS IN MUSCLE TRAINING

In treating weak muscles by means of active exercise there is always a danger of overtaxing and causing exhaustion which would hinder the progress of the recovery. So as to minimize this danger it has been found helpful to employ certain procedures with an aim to lessen the factors of gravity and friction. I

will mention those commonly employed, which in turn may suggest others to the reader:

(*a*) *Postural.*—The aim is to place the body in a favorable position, thereby eliminating gravity to a greater or lesser extent. For example, in treating a weak deltoid muscle the patient is placed on his back with the arm to the side resting on a smooth board covered with talcum powder. The arm may then be brought to a 90 degree angle, which the patient could not do in a standing position without a severe strain on the deltoid muscle. Similarly in treating a leg the heel may be placed on a roller skate, a piece of board with gliders underneath or a thin rubber sponge. The patient is now able to abduct and adduct the leg and flex the knee, gravity having been eliminated and friction having been reduced to a minimum.

(*b*) *Sling Suspension.*—Still another method is to suspend the extremity in a sling about 6 inches from the bed or table, thus removing the element of gravity. Again in this position the leg may be abducted and adducted and the knee flexed with comparative ease and without straining the muscles involved. In my experience I have found it helpful to attach to the lower end of the sling a 1 inch band of inner tubing, which gives opportunity for increased amplitude of motion. It also adds the element of resistance, which is desirable.

(*c*) *Underwater Exercises.*—These movements are performed in therapeutic pools or a tank constructed for home use.[2] Exercise in the pool must not be confused with swimming. It is useful because the buoyancy of the water lessens gravity and makes possible the application of therapeutic exercise.

(*d*) *Muscle Testing.*—In preparing a plan of muscle reeducation it becomes essential (*a*) to learn to what extent the muscles have been damaged in order to ascertain their capacity for work and (*b*) to keep in mind certain characteristic muscle reactions. As an aid to the former the following classification of muscles may be used or modified by giving each group a numerical value:

1. A normal muscle: patient can overcome gravity and resistance.
2. A good muscle: patient can overcome gravity and resistance, but less than normal.
3. A fair muscle: patient can overcome gravity only.
4. A poor muscle: patient can produce movement only with gravity eliminated.
5. A trace: contraction of muscle can be palpated but with only little or no motion.
6. Gone or total paralysis: no contraction felt.

Once the strength of a given group of muscles has been found and properly grouped, the selection and execution of correct remedial movements should be governed by well known principles of muscle action. A muscle group in need of strengthening should not be called on to perform its maximum load at the beginning of training; the capacity for work is greater if at no time the muscle is pushed to its limit; it is more desirable to exercise often for short periods rather than a few times for long periods.

Since it is of great importance to guard against exhaustion, special attention should be focused on the following precepts: Exercise may be carried to the point of fatigue, but not beyond; the greater the frequency of contraction, the more rapid the approach of fatigue; the more complete the exhaustion, mental or muscular, the longer the period necessary for recovery; and the more complex the discriminations required in a performance, the more rapid the onset of fatigue.

600 South Kingshighway Boulevard.

2. The Council on Physical Medicine will send free directions for the construction of a tank. Handbook of Physical Medicine, American Medical Association, 535 North Dearborn Street, Chicago.

Council on Foods and Nutrition

OCTOBER 1944 MEETING OF THE COUNCIL ON FOODS AND NUTRITION

The meeting of the Council on Foods and Nutrition was held in Chicago on Oct. 22, 1944 and was attended by the following members:

Dr. George R. Cowgill	Dr. Irvine McQuarrie
Dr. C. A. Elvehjem	Dr. Lydia Roberts
Dr. Philip C. Jeans	Dr. Russell M. Wilder
Mr. Culver S. Ladd	Colonel John B. Youmans
Dr. James McLester, Chairman	Dr. George K. Anderson, Secretary

In addition to members of the headquarters staff there were present as invited guests Dr. E. M. Nelson of the Food and Drug Administration and Dr. Donald A. Wallace, secretary of the Council on Dental Therapeutics of the American Dental Association. Two members of the Council, Dr. Morris Fishbein and Dr. Howard B. Lewis, were unable to be present.

Among the numerous topics which were discussed at the meeting, the following may be of interest to physicians, manufacturers and others:

Nutritional Aspects of Candy Advertising.—Considerable time was devoted to discussion of the question of candy advertising in publications of the American Medical Association. Advice will be given the Advertising Committee for its guidance in passing on the suitability of the nutritional statements of the candy advertising.

Suggestions were made for revisions in the so-called "Nutritional Platform for Candy." It was the opinion of the Council that the primary purpose of developing a nutritional story in candy advertising should be the education of the public in the judicious use of candy as a food substance rather than to increase the overall consumption of candy. It was felt that recommendations for the use of candy by young children can only be detrimental to their proper nutrition.

Food Comparisons in Advertising.—A technic which has been frequently used in the advertising of certain foods is the comparison of their nutritive values with several other types of foods. This method can be informative and educational or may be misleading to the reader, depending on the manner in which the material is presented. In some cases the impression may be gained that the advertised food supplies all the food values of the foods shown. This is highly undesirable. The Council was of the opinion that the practice of making comparisons in food advertising in general could not be considered desirable. If this type of advertising is used it should not give a misleading impression to the reader, and the comparisons made should not be derogatory to other good foods.

Vitamin A Content of Margarine and Butter.—The Council was informed of the recently determined average values for vitamin A content of winter and summer butters throughout the country. Other figures given by the Committee on Food Composition of the National Research Council show a vitamin A content of 10,000 U. S. P. units per pound for winter butter and 18,000 units per pound for summer butter. All of these figures are higher than previously determined values for butter and higher than the 9,000 units of vitamin A added to each pound of oleomargarine. This newer information on the vitamin A content of butter is of considerable interest because the minimum level of addition to margarine was set by the Food and Drug Administration to approximate that of average butter. The question was raised as to whether it would be advisable to encourage the addition of higher levels of vitamin A to margarine by extending use of the Council Seal to margarines fortified with 15,000 units of vitamin A, the equivalent of the year round average for butter. This was not considered advisable at the present time.

Under existing standards the fortification of oleomargarine with vitamin A is entirely optional. The almost universal fortification of table margarines with vitamin A by manufacturers at present is very commendable. It is felt, however, that provision should be made for the continued fortification of all margarine, since its nutritional value is dependent on an appro-

priate vitamin A content. With this objective a resolution was adopted urging that all margarine contain not less than 9,000 units of vitamin A per pound and that the Food and Drug Administration be requested to hold a hearing for the purpose of considering a proposal to have the present optional fortification of margarine with vitamin A be made a part of the standards of identity and of quality for margarine.

Vitamin A Addition to Milk.—This subject was discussed at the previous meeting and the conclusion reached that fortification of winter milk with vitamin A was not indicated in the interests of the public health. Instead, it was felt, encouragement should be given to those concerned with improving dairy feeding for the purpose of raising the vitamin A content of the milk. There has been some comment since the earlier meeting on the practicability of raising the vitamin A content of milk by improved feeding. It appears that improvement may not be possible to the degree or extent that was suggested earlier. This fact does not alter the position taken by the Council, which reaffirmed its original decision that fortification of winter milk with vitamin A is not necessary from the public health point of view.

Acceptability of Foods with High Natural Vitamin C Content.—Citrus and tomato juices are important dietary sources of vitamin C, and the Council has encouraged their use for the contribution of this vitamin which they make to the diet. Many such canned juices carried the Seal of Acceptance until the limitation of scope to special purpose foods excluded them from consideration. Numerous studies of canned tomato juice have shown a wide variation in values for vitamin C. This is attributed to differences in variety grown, climatic conditions and efficiency in processing methods. At present it is impossible for the consumer to determine the quality of canned tomato juice with respect to vitamin C.

It is the desire of the Council to encourage the marketing of high quality natural foods. This can be done in part by granting acceptance to products which meet high standards set by the Council. Tomato juice was selected as a food in which improvement should be sought by considering granting the Seal of Acceptance to brands which meet a high standard of vitamin C content. The value which was determined on as representing a high natural level was 20 mg. of vitamin C per hundred cubic centimeters. It was decided that this information should be communicated to manufacturers to secure their interest in the proposed program as well as their comments. At the same time a committee of the Council was appointed to work out the details of control necessary to insure that accepted brands meet the standards as well as to give consideration to the application of this policy to citrus juices and other foods.

Resolution for Continuance of Baked Goods Enrichment.—The Council has long been on record in favor of the enrichment of flour and baked goods and has done much to extend this practice. At the present time by order of the War Food Administration all white bread and rolls are enriched, but this requirement is effective only for the duration of the present emergency. Attention is now directed by those interested in providing for the continuance of these nutritional benefits to measures which will assure the perpetuation of enrichment. This can be accomplished by means of legislation in each of the individual states or through adoption of federal standards requiring enrichment. A combination of the two procedures may be the most effective.

To encourage action by the proper federal and state agencies the Council adopted a resolution urging that all white bread offered for sale contain the required quantities of enriching ingredients. It was further resolved that the Food and Drug Administration be requested to hold a hearing to consider a proposal that the present and proposed standards for bread, white bread, enriched bread and enriched white bread under the Federal Food, Drug and Cosmetic Act be merged and recognized as synonymous. At the same time it was recommended that state legislatures, particularly those not now requiring or authorizing recognition of federal food standards, enact legislation to accomplish the desired purpose within their boundaries.

Use of the Term "Pure" in Relation to Evaporated Milk.—It has been the declared policy of the Council to permit use of the term "pure" on labels or in advertising of only those accepted products for which definite standards of purity exist and when the product has been demonstrated to meet these standards. Permission has been sought for use of this descriptive term in connection with evaporated milk manufactured under the sanitary code of the Evaporated Milk Association. Opinions as to adequacy of the requirements of the code for serving as standards of purity for evaporated milk were presented to the Council. Since there was lack of agreement concerning the acceptability of the controls of the sanitary code as suitable standards of purity, the proposal that the word "pure" be permitted was not adopted. It was decided that the matter be held over for further study.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its actions will be sent on application.

AUSTIN SMITH, M.D., *Secretary.*

STAPHYLOCOCCUS TOXOID-VACCINE MIXTURE.—A mixture containing in each cubic centimeter 2,000 million killed Staphylococcus aureus and the staphylococcus toxoid derived from 1,000 necrotizing doses of toxin.

Actions and Uses.—Staphylococcus toxoid-vaccine mixture is used in infections of recognized staphylococcic etiology. Such a mixture has been offered to neutralize the toxin and lysis of the invading organism. Local reactions may follow injection.

Dosage.—Ten doses, the first dose being 0.1 cc. (200 million Staphylococcus aureus, staphylococcus toxoid 100 necrotizing doses), the tenth 1.0 cc. Each dose is increased by 0.1 cc. The agent is given subcutaneously at weekly intervals.

THE NATIONAL DRUG CO., PHILADELPHIA

Vatox Staphylococcus Toxoid-Vaccine: 6 cc. vials. Preserved with merthiolate 1:10,000.

PENICILLIN (See Supplement to New and Nonofficial Remedies, 1944, p. 18).

The following dosage forms have been accepted:

MERCK & CO., INC., RAHWAY, N. J.

Penicillin (Calcium Salt): 100,000 Oxford Unit vials.

Penicillin (Sodium Salt): 100,000 Oxford Unit vials.

THE WM. S. MERRELL CO., CINCINNATI

Penicillin Sodium: 100,000 Oxford Units.

ELI LILLY & CO., INDIANAPOLIS

Penicillin (Calcium Salt): 100,000 Oxford Unit *ampuls.*

CHAS. PFIZER & CO., INC., BROOKLYN

Penicillin (Sodium): 100,000 Oxford Unit bottles.

BACTERIAL VACCINE MADE FROM THE CHOLERA VIBRIO (CHOLERA VACCINE) (See New and Nonofficial Remedies, 1944, p. 568).

The following dosage form has been accepted:

ELI LILLY & CO., INDIANAPOLIS

Cholera Vaccine: 20 cc. vial. Each cubic centimeter contains 8,000 million killed cholera vibrios.

BOTULISM ANTITOXIN (See New and Nonofficial Remedies, 1944, p. 536).

The following dosage form has been accepted:

LEDERLE LABORATORIES, INC., NEW YORK

Botulism Antitoxin Bivalent Globulin Modified: Vial containing 10,000 units each of type A and type B botulism antitoxin. Preserved with phenol 0.4 per cent and 1:25,000 phenylmercuric borate.

NIKETHAMIDE (See New and Nonofficial Remedies, 1944, p. 330).

The following dosage form has been accepted:

CARROLL DUNHAM SMITH PHARMACAL CO., ORANGE, N. J.

Solution Nikethamide 25% W/V: 15 cc. vials.

SATURDAY, MAY 19, 1945

THE RETURNING MEDICAL OFFICER

Under Medicine and the War in this issue of THE JOURNAL appears a message from Surgeon General Norman T. Kirk indicating that it will be the policy of the Army Medical Department to bring back to the United States medical officers relieved from service in the European theater of operations and to assign them on their return, as long as needed, to service in their specialties in American hospitals and other installations. Medical officers who have not had foreign service and who are found fit for service abroad will be assigned as needed to foreign theaters of operations. This information will answer the questions of many medical officers, some of whom have written and telegraphed to the headquarters of the American Medical Association asking for a definite statement on this subject.

Many physicians have also written to the American Medical Association protesting against the possibility that they may be assigned on their release from service with the armed forces to the Veterans Administration. These letters were brought before the Committee on Postwar Medical Service at its meeting in Chicago May 12. That committee took prompt action, adopting the following statement, which was sent to the Secretary of War, Secretary of the Navy and the Committees on Military Affairs of the House of Representatives and the Senate:

In November 1944 the Army Medical Department was directed to transfer at least 300 medical corps officers to the Veterans Administration, this number to include those officers in the zone of the interior who were formerly employed by the Veterans Administration as civilians. Apparently about 100 men meeting the latter classification were so assigned and in addition some 200 others selected largely from among men who had been marked "limited service." Many of those thus assigned have protested and others are now protesting bitterly against these assignments on the ground that their enlistment was distinctly for military service and that assignment to the Veterans Administration cannot be thus characterized. Many physicians who have served with distinction in both the European and the Pacific theaters of operation are now indicating by communications addressed to the headquarters of the American Medical Association the fear that they may be assigned on their return to the United States to service with the Veterans Administration. The unwillingness to serve with the Veterans Administration is based not only on their belief that this cannot be considered military service but also on the point of view that competent, scientific medical care is difficult under the conditions that prevail in the veterans' hospitals.

The Committee on Postwar Medical Service, which includes representatives of the American Medical Association, the American College of Surgeons, the American College of Physicians, the American Hospital Association, the Federation of State Medical Licensing Boards, the Association of American Medical Colleges, the Catholic Hospital Association, the Advisory Board for Medical Specialties and many other groups, after careful consideration of the problems involved urges that the Secretary of War, the Secretary of the Navy and all others concerned with the activities of physicians voluntarily enlisted in the armed forces recognize the righteousness of the protests made by these medical officers against assignment to the Veterans Administration. It is further urged that the needs of the Veterans Administration for physicians be met either by voluntary enrolment of men in the armed forces at the time of their release from the service or by recruitment of medical personnel from civilian sources.

The American Medical Association—and this statement is made wholly in explanation of a fact that should be obvious to every one—does not have authority to determine in any way the assignments of physicians in the armed forces. The officers of the Association would be hesitant to interfere in the making of decisions as to the assignments or transfer of men in the armed forces. The decisions as to how military personnel are to be utilized must rest with those who carry the responsibility for the ultimate results. This statement is made because many a medical officer has written to the headquarters of the American Medical Association actually demanding that the Association exert its influence to determine the decisions, not only of those responsible for the medical departments of the armed forces, but even of the Secretaries of War and Navy, of the Committees on Military Affairs of the legislative bodies and even of the President. The Board of Trustees and the officers of the Association have felt keenly, nevertheless, the responsibility that rests on them to present to those in authority the facts that should be given serious consideration in the making of decisions concerning medical personnel.

Unfortunately, steps have not yet been taken by the Selective Service System for a continuing supply of physicians for the future. The medical schools are confronted at this moment with an insufficient number of men to fill their freshman classes in the years immediately to come. The Committee on Military Affairs of the Senate, having given serious and extended hearings to the Ellender bill, has failed to issue a statement of its reaction to that proposal. The time may yet come when those with the authority and the responsibility will have to answer to the people of the United States for a critical situation in the supply of medical service.

NUTRITIONAL EDEMA

A characteristic edema appears widespread during war and famine. This war is not an exception. None of the usual designations, as famine edema, war edema, hunger edema and nutritional edema, express adequately the nature of the disease Until recently biochemical and nutritional knowledge has been inadequate to determine a more specific cause than nutritional deficiency.

The relationship of lowered blood protein to the development of edema was pointed out by Starling in 1896; the protein factor has received increasing attention in the last decade. Edema from lack of thiamine occurs in the wet type of beriberi. One or both of these factors may be involved in the development of the edema observed during famine.

In some persons with this edema the serum protein was determined [1] and an average value of 5.39 per cent was found, compared with 8.07 for the normal or average. Other reports describe only the presence of edema and the effect of various therapeutic agents in causing it to disappear or body weight to decrease. The efficacy of high protein foods in raising the serum protein values and in causing the edema to disappear is generally acknowledged. Casein and soy flour in amounts of 150 and 300 Gm. respectively added to a standard 1,700 calory diet were found effective in causing edema to disappear.[2] The addition of 2.5 liters of milk to the daily diet of 11 patients resulted in some recoveries. Vallejo successfully treated cases of malnutrition edema with the addition of 1.5 liters of milk daily to a 1,900 calory diet containing 35 Gm. of protein. The addition of butter to the basic diet was helpful in relieving edema; the authors attribute this effect to the protein sparing action of this fat Investigators who study these patients caution against the relapse that often occurs if treatment with protein is discontinued soon after the edema is lost. This observation supports the concept that lowered serum proteins indicate a depletion of protein reserves of the body which must be restored before cure can be effected

The results of attempts to relieve nutritional edema by administration of vitamins of the B complex are conflicting. Several workers report that improvement of the edema does not follow the use of parenteral injections of as much as 75 mg. of thiamine or 1 Gm. of niacin daily for ten days.[2] Crismer [3] found that the urinary excretion of thiamine in 6 patients with hunger edema was the same as that of healthy persons with normal thiamine excretion after saturation tests. Such symptoms of thiamine deficiency as numbness and paresthesias were usually absent. In contrast are the reports of Simonart,[4] in which the claim that thiamine is effective in relieving the edema and has an influence on the protein level of the blood is made repeatedly. Some of the experiments of this investigator are complicated by the fact that the brewers' yeast used as a source of thiamine is a good source of high quality protein as well. The preponderance of evidence points to the dominant role of protein in the etiology of this type of edema.

Opportunity is afforded in the rehabilitation of European countries to study this problem further. The final answer will establish the part played by each of the nutritional factors. When the causative relationship has been determined satisfactorily this condition may be designated by a term which describes the nutritional state accurately.

EPIDEMIOLOGICAL INFORMATION BULLETIN OF THE UNRRA

The Council of the United Nations Relief and Rehabilitation Administration recommended in November 1943 that government and recognized national authorities cooperate fully with the administration in establishing, at the earliest possible date, regional and other emergency agreements and arrangements for the notification, within the limits of military security, of diseases likely to become epidemic, uniformity in quarantine regulations and for other measures of prevention. An Expert Commission on Quarantine was appointed by the Standing Technical Subcommittee on Health for Europe on May 12, 1944 with instructions to draft, for consideration by the Subcommittee on Health, international sanitary agreements of an emergency nature designed to take effect at the earliest possible date and to continue through the immediate postwar period. The two principal existing international treaties relating to quarantine were the International Sanitary Convention, signed at Paris in 1926, and the International Sanitary Convention for Aerial Navigation, signed at The Hague in 1933. After studying the existing conventions and the modifications required to make them conform to the conditions arising from the war, the commission realized that such modifications should also be applied worldwide if they were to be effective. The commission submitted to the Standing Technical Subcommittee on Health for Europe, at its meeting on May 19, 1944 two drafts with an explanatory memorandum for the modification of the International Sanitary Convention, 1926, and the International Sanitary Convention for Aerial Navigation, 1933. Each draft provided that UNRRA would carry out the duties and functions assigned to the International Office of Public Health, Paris, without prejudice to the future status of that body. To give greater amplitude to the amended conventions, governments would notify, in addition to the diseases specifically mentioned in the previous conventions, namely plague, cholera, yellow fever, typhus and small-

pox, other communicable diseases which, in the opinion of UNRRA, constitute a menace to other countries, and would keep the administration regularly informed of the course of the epidemic. In turn, UNRRA would promptly inform all participating governments of the outbreak of any disease which, in its opinion, constitutes a menace to other countries and of the measures which are being taken to prevent the spread of the disease across frontiers.

In January 1945, when the Health Division of UNRRA was entrusted with the execution of the amended international sanitary conventions, the director general of UNRRA requested that the staff of the Health Research Unit of the League of Nations be released for transfer to the UNRRA's Health Division in order to form the nucleus of its epidemiologic information service to be organized within the section of epidemic control. The *Epidemiological Information Bulletin* is to be the medium of information to those concerned. Its first few issues, according to Wilbur A. Sawyer, director of health, will consist pricipally of the authentic texts of the new and amended sanitary conventions. Subsequently the statistical material will be regularly presented and space will be given to reports on epidemic control activities in which UNRRA may be taking part, to certain reports and resolutions of the Standing Technical Committee on Health and its Expert Commission on Quarantine, and to such items of news as may have special bearing on international health.

The *Epidemiological Information Bulletin* will serve to bring about more effective and intimate collaboration between nations in control of disease.

Current Comment

ANTIVIVISECTIONISTS DEFEATED IN BALTIMORE

Nowadays, whenever state legislatures are in session, so-called "dog bills" are introduced through the pressures exerted by the executive secretaries of groups who call themselves antivivisectionists. These sentimentalists have adopted the dog as the symbol of their approach to an antiscientific crusade against medical research involving the use of animals. The crusade is based on the claim that research involving animals is needlessly cruel and should therefore be prohibited. Moreover, the benefits to medical science and therefore to sick human beings are said to be fictitious. Our legislators are drawn largely from nonmedical groups and are likely to be uninformed about medical research. From the antivivisectionists' point of view they are ripe for the picking. Most legislators, however, are definitely susceptible to facts when well presented. According to the Baltimore *Sun*, April 10, the city council adopted an unfavorable report of its committee on legislation with respect to a proposed ordinance which would have prohibited the use of live dogs for experimental purposes in medical schools and laboratories in the city of Baltimore. The action of the committee was adopted by the council without discussion. Previously there had been a three hour hearing in which the matter was exhaustively explored. The council chamber was filled with proponents and opponents of the ordinance. Many of Baltimore's leading physicians, including the deans of the faculties of medicine of Johns Hopkins and the University of Maryland, the city health commissioner and many others, attended. These physicians told of the use of animals and the necessity for their use in connection with much modern progress in medicine, such as establishing the dosages of the sulfonamide drugs, testing of epinephrine and the treatment of shock with plasma. The most effective testimony was the introduction of two children and the mother of a third whose lives had been saved through blood vessel surgery by Dr. Alfred Blalock of Johns Hopkins. The *Sun*, in addition to publishing a lengthy report of the council action, made it the subject of an editorial comment in its next issue, April 11. Significant statements from the editorial are the following:

> On Monday night the city council killed the proposed antivivisection ordinance. . . . In so doing the council did the intelligent thing. . . . The campaign to prohibit the use of dogs in medical experiments is particularly vicious because it appeals to unthinking sentimentality. . . . Such an ordinance as that which the council just killed would be a fearful blow to scientific research and, indeed, would stop research entirely in many lines. It is an attack on enlightenment and on the humane objectives of research. *The antivivisection movement is inhumane in the deepest sense.* . . . Baltimore is one of the world's great centers of medical research, and the men engaged in it decided to lay their case before the city council fully and frankly. Like good scientists, they placed their faith in the power of reason to convince all men of good will . . . and the council by its prompt decision fully justified their faith.
>
> Many morals might be drawn from this episode. One is that, in the defense of enlightenment, there must be a never ceasing vigilance and that no man, however remote he may feel himself from the turmoil of politics, can properly consider himself above the fight. Another is that reason—in which so many, confronted by the power of unreason in this turbulent world, seem to have lost faith—is still a shining weapon.

Baltimore is to be congratulated on this victory for reason and science over the sinister forces arrayed against medical research and the progress of medical science. The tragedy is that the fight in Baltimore will have to be made again and again before state legislatures, city councils and the Congress. Ignorance, fanaticism, false sentimentalism and cynical irresponsibility are diseases for which science has thus far failed to find a remedy, even with the use of experimentation on animals that has yielded so much good to both animals and man.

MEDICINE AND THE WAR

ARMY

CIVILIAN COMMITTEE TO AID ARMY IN REHABILITATING BLIND SOLDIERS

The War Department recently announced that, in its efforts to rehabilitate blinded soldiers of the present war, the Army will be assisted by an honorary civilian advisory committee selected by the Surgeon General from among leaders in work among the blind throughout the United States. Addition of the advisory services of this committee emphasizes the determination of the Surgeon General that no blinded soldiers of this war will be returned to their communities without maximum adjustment and aid in the resumption of a normal and useful life in their respective communities.

Services of the members of the committee will be available to Dibble General Hospital at Menlo Park, Calif., and Valley Forge General Hospital at Phoenixville, Pa., which are the medical and surgical centers for blinded servicemen, and to Old Farms Convalescent Hospital, Avon, Conn., the Army's center for rehabilitation training for blinded veterans.

Function of the committee will be to advise the Army in the technic used in civilian organizations for the blind, to offer suggestions which may be adapted to army use and to be of general assistance to those in charge of the Army's program, so that effective liaison with the civilian agencies for the blind may be maintained.

Three members of the committee, Peter J. Salmon, Brooklyn; W. L. McDaniel, Washington, D. C., and Henry Johnson, Tampa, Fla., have been appointed special consultants to the Surgeon General and will make a field survey of the Army's program for the Medical Department.

The other members of the committee are Robert B. Irwin, chairman, New York; Josef G. Cauffman, secretary, Overbrook, Pa.; Gabriel Farrell, Watertown, Mass.; Eber L. Palmer, Batavia, N. Y.; Roma S. Cheek, Raleigh, N. C.; Mrs. Lee Johnson, Jefferson City, Mo.; E. A. Baker, Toronto; Thomas J. Carroll, Newton, Mass., and Philip N. Harrison, Harrisburg, Pa.

Rotation and Redeployment of Medical Officers

The policy of the War Department and of my office is that when medical officers are returned to the United States on rotation or redeployment they will be assigned to duty according to their specialties. They will replace officers with similar qualifications who have not had opportunity for foreign service.

KIRK
Office of the Surgeon General
Washington, D. C.

TWO WOMEN DOCTORS ASSIGNED TO SURGEON GENERAL'S OFFICE

Among the medical officers recently assigned to the Surgeon General's Office are two women doctors, Capt. Gladys Osborne, M. C., Waynesville, N. C., and 1st Lieut. Audrey A. Bill, M. C., Wayland, Mass.

Captain Osborne is assigned to temporary duty with the Nutrition Division. She graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1932, was commissioned in the Medical Corps in 1943 and has been a medical ward officer at Lawson General Hospital, Atlanta, Ga., and prior to her present assignment was admitting and dispensing officer and chief of the outpatient service at Foster General Hospital, Jackson, Miss.

Lieutenant Bill is assigned to the Preventive Medicine Service. She graduated from Boston University School of Medicine in 1941 and entered the service July 29, 1943. Her army assignments have included duty at the Station Hospital, Fort Devens, Mass., and Waltham Regional Hospital, Waltham, Mass., where she was in the surgical service.

EXHIBIT ART WORK CREATED BY ARMY DOCTORS

The première exhibit of more than two hundred and fifty oil paintings, water colors and sketches depicting the war role of army doctors, nurses and enlisted men of the Army Medical Department was held at the Corcoran Galleries, Washington, D. C., May 13.

The pictures are the work of several of the country's foremost artists. They make up the Army Medical Department War Art Project, which was authorized by the War Department two years ago and launched at the same time by the Surgeon General's Office. Many of the artists, who worked on the project under the direction of the Associated American Artists in New York, were sent to American battle fronts in the South Pacific, Europe and the Mediterranean. Others confined their activities to training centers in the United States and to zone of interior hospitals.

The idea for a collection of Army Medical Department war paintings was first projected in September 1942 by Lieut. Col. Howard Baer, executive officer of the Army Medical Purchasing Department Office, New York branch of the Surgeon General's Office. With the aid of his commanding officer, Col. Howard F. Currie, currently executive officer, Supply Service, Office of the Surgeon General, approval of the undertaking was obtained from Major Gen. Norman T. Kirk, Surgeon General of the United States Army, and the office of the Secretary of War. Colonel Baer was charged with the duty of propelling the project to a successful conclusion.

The project was sponsored by Abbott Laboratories. Known as the Abbott Collection of Paintings of Army Medicine, the canvases will be donated to the War Department.

The entire collection will be exhibited in several large cities. Although the exhibiting itinerary has not been completed, the collection will move from Washington to St. Louis in June. Other cities in which the pictures are scheduled for exhibition include New York, Seattle, Chicago, Cleveland, San Francisco and New Orleans.

INTRASTERNAL PLASMA SAVES CREWMAN'S LIFE

The life of a B 29 crew man was recently saved when comrades gave him blood plasma through a new type of needle. The successful injection showed that the new intrasternal method of administering plasma can be used safely by airmen. The intrasternal method is being taught to the entire crew even before they start on bombing missions, so that this method can be resorted to when the patient is suffering from shock and his veins have collapsed.

SANITARY CORPS OFFICER AWARDED LEGION OF MERIT

Major Joseph A. Calamari, Sn. C., was recently awarded the Legion of Merit for determining through personal investigation the causes of corrosion of stainless steel and plated carbon steel surgical instruments, both in storage and in the field, causing failure or impairing the usefulness of the instruments. As a result of the investigation, Major Calamari devised a method of prevention which will protect the maximum usefulness of surgical and dental instruments.

MEDICAL DEPARTMENT WOMEN RETURN FROM INSPECTION

The heads of the three professional women's corps of the Medical Department have recently returned from an extensive tour of inspection of hospital and nurses' facilities in the European and Mediterranean theaters of operations. Those on the trip were Col. Florence A. Blanchfield, superintendent of the Army Nurse Corps; Major Emma E Vogel, chief of the Physio-Therapy Division, and Major Helen C. Burns, chief of the Dietetic Branch.

DENTAL CORPS OFFICER WINS AWARD

Major Victor H. Dietz, formerly of St. Louis and now in the Army Dental Corps, was recently awarded the Legion of Merit in recognition of his work in perfecting a plastic substitute for making artificial eyes.

ARMY AWARDS AND COMMENDATIONS

Colonel Benjamin J. Birk

Col. Benjamin J. Birk, formerly of Milwaukee and now surgeon of headquarters of the CCC near Kunming, China, was recently awarded the Legion of Merit "for exceptionally meritorious conduct in the performance of outstanding services." For a time before arriving in India in February 1944 Dr. Birk was commanding officer of a hospital troop ship. Flown over the Himalayan "hump" to China in April 1944, he served as medical officer with an American liaison group attached to Chinese combat forces in the fighting about Kweilin, Changsha, Henyang, Chaun Shien and Luichow in the spring, summer and early fall of 1944. Dr. Birk graduated from Rush Medical College, Chicago, in 1919 and entered the service in April 1942.

Colonel Robert S. Brua

The Legion of Merit was recently awarded to Col. Robert S. Brua, formerly of Los Angeles. According to the citation "he served as division surgeon of the Alaskan Division, Air Transport Command, from July 1943 to October 1944. With rare ability he made plans for, established and maintained a medical department that contributed in great measure to the highly successful operations carried out by the Alaskan Division. Surmounting the obstacles of climate, terrain and transportation difficulties, he established dispensaries in isolated localities and organized all medical aspects of the search and rescue work. Under his supervision the water problems which threatened the health of the personnel were effectively solved and a well coordinated system instituted for the air evacuation of the wounded and sick from the widely scattered areas." Dr. Brua graduated from Washington University School of Medicine, St. Louis, in 1931 and entered the service July 1, 1934.

Captain Shermer H. Stradley Jr.

The Legion of Merit was recently awarded to Capt. Shermer H. Stradley Jr., formerly of Wilmington, Del. The citation commends Captain Stradley for "exceptionally meritorious conduct in the performance of outstanding service in North Africa, Sicily and Italy from March 13, 1943 to Aug. 26, 1944. From the activation of the battalion he organized, trained and constantly supervised the medical detachment including regular and emergency aid men in all companies. The excellent state of general health and extremely low time lost for disease and malaria in highly infected areas kept the effective manpower of the battalion at such a high percentage that the unit was able to lead or equal all similar transportation battalions in ton-miles of essential war supplies through three different campaigns. Captain Stradley attained these results through constant study of newest methods, through personal and energetic inspection and supervision of all health and sanitary measures, by constant instruction and supervision of preventive measures, and through the building up of complete confidence in all the personnel of the battalion. His actions are in keeping with the highest traditions of the United States Medical Corps." Dr. Stradley graduated from Hahnemann Medical College and Hospital of Philadelphia in 1934 and entered the service in June 1942.

Colonel Francis J. McGowan

The Bronze Star was recently awarded to Col. Francis J. McGowan, formerly of New York, "for meritorious achievement in connection with military operations against the enemy on Leyte, Philippine Islands," and five days later he was awarded the Oak Leaf Cluster to the Bronze Star for his actions, including performance of operations under fire as a volunteer on Luzon, Philippine Islands, where he was attached as an observer with the forces commanded by Major Gen Charles P. Hall. The Luzon citation states, in part, "Owing to a critical shortage of qualified surgeons, Colonel McGowan volunteered his services and was on four occasions assigned to different portable surgical hospitals where his services were most needed. During this entire period he was on duty extremely long hours performing many delicate and serious operations and, through his knowledge and skill, was instrumental in saving many lives. In many instances he was working very near the enemy lines and was exposed to enemy sniper, machine gun and mortar fire. His devotion to duty, his calm and efficient manner under the strain of combat and his superior surgical skill contributed in a large degree to the success of the operation and was an inspiration to his comrades. His actions were in keeping with the highest traditions of the military service." Dr. McGowan graduated from Columbia University College of Physicians and Surgeons, New York, in 1921 and entered the service Oct. 2, 1942.

Major Sylvester W. Rennie

Major Sylvester W. Rennie, formerly of Wilmington, Del., was recently commended by his commanding officer, Major Gen. R. G. Breene. The commendation read, in part, "During the evacuation of wounded troops from Guadalcanal through the 27th Station Hospital this officer displayed extraordinary ability as a surgeon and extreme resourcefulness in coping with situations which at the time, owing to limited equipment, seemed hopeless. By his untiring energy and devotion to duty he set an example for the enlisted men and was one of the four surgeons who went without rest or sleep for eighty-six hours. As a result of the cooperation and skill of this officer over 140 badly injured soldiers were given expert surgical care. Wounds of the extremities, chest and abdomen were all operated on successfully and most of these men were evacuated by troop ship to the United States for further care within seven days." Dr. Rennie graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1930 and entered the service in June 1942.

Major Robert W. Robertson

Cited many times for his performances as a surgeon at the battle front, Major Robert W. Robertson, formerly of Paducah, Ky., was recently decorated as an Honorary Officer of the Military Division of the Most Excellent Order of the British Empire. The honor came from His Majesty, the King of England, and it is the first of its kind to be presented to an American medical officer. The decoration was bestowed "in testimony of Major Robertson's outstanding performance while on duty for four and a half months as operating surgeon in a British Field Hospital at the Anzio beachhead." An appropriate ribbon was presented to Major Robertson by the com-

manding officer of the Second Auxiliary Surgical Group, in lieu of the insignia and the medal which will be presented at a later date by a high ranking British official. It was stated that King George notified General Alexander to present the medal formally when the tactical situation permits. Dr. Robertson graduated from Loyola University School of Medicine, Chicago, in 1932 and volunteered for service in September 1942.

Major Joseph M. Greene

The Purple Heart was recently awarded to Major Joseph M. Greene, formerly of Chicago, who is now somewhere in Germany attached to the 105th Evacuation Hospital, which was bombed by enemy aircraft Dec. 31, 1944. Dr. Greene graduated from Rush Medical College, Chicago, in 1927 and entered the service June 1, 1942.

MISCELLANEOUS

MILITARIZATION OF THE AMERICAN HOSPITAL IN PARIS

THEODORE C. MERRILL, M.D.
Ancien associé en médecine de l'Hôpital américain de Paris

The American Hospital in Paris on Neuilly-sur-Seine has temporarily suspended its functions as a civic hospital. At present it is governed by the military authorities of the United States as represented by Lieut. Col. Edmund O. Gates, chief medical officer. A few officials of the old régime will continue their functions alongside the personnel belonging to the Army of the United States. From now on the hospital will accept only members of the American forces.

The hospital was created in 1906 and conforms to the regulations pertaining to hospitals in France. It received its first patient on March 30, 1910 and was formally recognized in 1913 by a federal legislative decree of the United States. This first American hospital had a capacity of between 40 and 50 patients only. It rendered efficient service to the organization and work of the American Ambulance Hospital during the war of 1914-1918. After this war the necessity for an American hospital in Paris became more and more evident. A new building, commenced in 1922, was opened on Jan. 30, 1926, the inaugural ceremony having been held on May 12 of the same year. Subsequent to that date the hospital functioned in Paris until the entry of the United States into the present war. In 1941, following the departure of the American officials, the hospital was occupied by the French Red Cross and was used largely as the center of rehabilitation of the wounded, occasionally admitting a certain number of civilian patients. The hospital was incorporated to function as an American hospital in France for a term of fifty years, thirty-one of which have already elapsed. What will be its existence in the remaining nineteen years? Who knows? Perhaps it will be converted into a French hospital and perhaps its charter will be renewed and prolonged. In any case it will always be a part of the medical history of Paris.

We salute, therefore, the hospital under its new name—"Station hospital numéro 365 de l'armée des Etats-Unis" (Base Hospital No. 365 of the American Army) and wish it and its chief a future full of honor and usefulness.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced.

California

Birmingham General Hospital, Van Nuys. Traumatic Surgery of the Abdomen, Dr. Charles E. Phillips and Comdr. Gaylord Bates, May 23.

U. S. Naval Hospital, Santa Margarita Ranch, Oceanside: Malingering Tests, Dr. John Mackenzie, May 24.

U. S. Naval Hospital, Corona: Tumor Pathology, Comdr. John W. Budd, May 24.

U. S. Naval Hospital, Mare Island: Uremia Following Urologic Surgery, Dr. Donald Smith, June 8; The Surgical Approaches to the Knee Joint, Dr. LeRoy C. Abbott, June 15.

Station Hospital, Fort Ord: Psychosomatic Medicine, Dr. Karl Bowman, June 2; Abdominal Surgery, Dr. Thomas F. Mullen, June 16; Injuries to the Knee Joint, Dr. Frederic C. Bost, June 23.

Station Hospital, Stockton Army Air Base: Early Ambulation of Surgical Patients, Dr. H. Glenn Bell, June 13; Diagnosis and Treatment of Arthritis, Dr. Hans Waine, June 20; Injuries to the Knee Joint, Dr. Carl E. Anderson, June 27.

Station Hospital, Camp Roberts: Severe Infections of the Hand, Dr. Edmond D. Butler, June 16; Experiences with Infectious Diseases in Army Camps in England, Dr. Gordon E. Hein, June 23.

U. S. Naval Hospital, Treasure Island: Experiences with Infectious Diseases in Army Camps in England, Dr. Gordon E. Hein, June 1.

Hammond General Hospital, Modesto: Subacute Bacterial Endocarditis, Dr. William J. Kerr, June 13.

Kansas

A. A. F. Regional Hospital, Smoky Hill Army Air Field, Salina: X-Ray Findings in Abdominal Pathology, Dr. Ira H. Lockwood, June 14; Shock Burns and Blood Derivatives, Dr. Vincent T. Williams, June 1.

New York

Station Hospital, Mitchel Field: Treatment of Thyrotoxicosis, Dr. David P. Barr, June 4; Diagnosis and Treatment of Malaria, Dr. Henry E. Meleney, June 5.

Virginia

A. A. F. Regional Hospital, Langley Field: Gastroenterology, Dr. Lay Martin, June 29; Traumatic Surgery of the Abdomen, Lieut. R. C. Wood, June 29.

West Virginia

Newton D. Baker General Hospital, Martinsburg: Chest Injuries in War, Dr. I. A. Bigger, June 4; Shock, Dr. E. I. Evans, June 4; Liver Diseases Seen in the Present War, Col. Balduin Lucke, June 18.

Wisconsin

Station Hospital, Camp McCoy: Blood Dyscrasias, Malaria, Filariasis, Dr. O. O. Meyer, May 23.

Station Hospital, Truax Field: Brain and Spinal Cord Injuries, Dr. T. C. Erickson, May 23.

ONE TON ELECTRON MICROSCOPE

Surgeon Gen. Thomas Parran of the Public Health Service recently announced that a 1 ton electron microscope, powerful enough to magnify the windpipes of mosquitoes to a size of approximately 2 inches, was recently added to the arsenal of scientific instruments for the study of cancer at the National Cancer Institute, Bethesda, Md. Although installed in the National Cancer Institute, the microscope will not be restricted to the study of cancer but will be available to other divisions of the National Institute of Health.

The microscope was built by the Radio Corporation of America at a cost of $13,000 and is the ninetieth in this country. It uses electrons instead of light rays, and magnetic fields instead of glass lenses, to peer into submicroscope worlds. It has revealed for the first time how disease-fighting organisms in the blood attack disease-producing viruses. The highly magnified photographs—or electron micrographs, as they are termed—show how the body protects itself from infantile paralysis, smallpox, influenza, the common cold, yellow fever and other diseases. These micrographs are important factors in determining the effectiveness of various methods of treatment. The machine will also enable scientists to compare diseased tissues with healthy tissues under direct magnifications of 10,000 to 75,000 diameters.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

May 14, 1945.

Week of June 2 Proclaimed National Rehabilitation Week

Although overshadowed by the announcement of VE day at the White House, a proclamation was issued by President Truman making the week of June 2 National Rehabilitation Week. It will be the twenty-fifth anniversary of the national program for rehabilitating men and women returning from the armed forces with disabilities. President Truman called on all churches, educational institutions, health and welfare services, civic organizations, chambers of commerce, industry, radio, press and the public to join in the program.

Federal Security Administrator Paul V. McNutt announced that specially arranged clinics for the examination and treatment of disabled men and women would be held throughout the country between the 2d and 8th of June. Michael J. Shortely, director of the Office of Vocational Rehabilitation of the Federal Security Administration, will unite all cooperating state agencies in the program.

Possible Replacement of General Hines

Capital Hill sources say that President Truman may dismiss 66 year old Brig. Gen. Frank T. Hines as Veterans Administrator and replace him with his former Missouri Senate colleague Bennett Champ Clark, a veteran and former commander of the American Legion. Furthermore, Mrs. Edith Nourse Rogers, Republican of Massachusetts, ranking Republican on Representative John Rankin's House Veterans Committee, says that President Truman is "definitely interested" in her bill to create a new Department of Veterans Affairs, headed by a Secretary of Veterans Affairs in the cabinet. General Hines meanwhile has stated that the problem in veterans' hospitals today is not beds but personnel. He states that 1,000 more beds could be added if 100 more nurses could be found.

Medical Testimony Against Animal Experiments Sought

Representative Lemke, Republican of North Dakota, sponsor of the Lemke bill prohibiting experiments on live dogs or other animals in Washington, is seeking personal testimony or written statements against animal experiments from leading medical men. He revealed that hearings scheduled before a House District subcommittee have been deferred to about May 20 to enable him to get this testimony. Expressing confidence that the House will enact the legislation during this session, Representative Lemke said "Our witnesses, many of them among the best known practitioners in the nation, will show that most of the claims made for the scientific value of experiments on animals are baseless and unverified."

Studies in United States by Brazilian Health Official

Enrique Da Rocha Lima, superintendent of the Biologic Institute of São Paulo, stated on his arrival here from Rio de Janiero on invitation of the Department of State that he will make a thorough study of prevention and cure of typhoid and malaria. He will attend classes at Columbia University in New York and other colleges in the North and East. He will study animal and plant diseases at the Department of Agriculture in Washington. The Brazilian government, he said, is concentrating on a campaign against spread of all tropical diseases.

Probe of Government Spending for Research

Senator Homer Ferguson, Republican of Michigan, has started a one man investigation to determine whether government spending for research is justified. As a member of the Senate Appropriations Committee he wishes to know how much is being spent, whether there is waste or overlapping, and whether people are getting value for money spent. He found on checking through committee files a total government research budget of more than half a billion dollars. "I don't want to do anything to stand in the way of developing the most modern and efficient implements of war for the protection of our armed forces and the nation as a whole, but I think it's time to take stock of what we are doing" he said.

Doctors Maintain Health Despite Shortages

The District of Columbia Medical Society reports from a survey covering the period from Sept. 1, 1942 to April 1, 1945 that, despite a wartime decrease in private physicians, the remaining doctors are capably serving all patients and could meet an epidemic with the aid of hospital staffs and medical students. The survey was prepared by auditors of the U. S. Public Health Service in cooperation with the medical society for the Procurement and Assignment Service of the War Manpower Commission. The survey showed that the number of private practitioners dropped from 991 to 910 and the segment of population assigned to each rose from 934 to 1,018 in the city and 1,250 in the area. The present potential load is said to be closer to 1,400 at this date. One doctor in 1,250 was said to be the top desirable load but that through an increased effort on the part of practitioners the situation had been handled adequately. Dr. George C. Ruhland, District health officer, said that the general health seems to have increased rather than decreased in the capital.

Russian Hospitals for Amputee Cases

Russian War Relief, Inc., reports that it is spending more than $1,000,000 to equip a system of hospitals in the Soviet Union to handle amputation cases. The organization, an agency in the National War Fund, intends to equip four regional hospitals in different sections of the Soviet Union with artificial limb workshops where final fittings will be made. Dr. Vladimir D. Chaklin, director of the Prosthetics Institute of Moscow, has been in this country for the past five months consulting with American physicians and manufacturers of artificial limbs.

Improved Medical Aid for War with Japan

Experience of medical officers in the European theater will benefit work of service physicians and surgeons in the war against the Japs, it is revealed here. Besides improvements in battle technic, better equipment will be available. Two examples: The Medical Corps has built special portable dental units that can be used as operating rooms, and sterilization units that can be converted into a heating plant large enough to keep a whole hospital warm.

Capital Notes

Although the Catholic clergy have opposed the proposal to legalize sterilization of mental defectives in the District of Columbia, Rev. Edward Oliver Clark, Baptist, has urged in a letter that District commissioners proceed to draft legislation.

More than 200 representatives of five sponsoring groups attended the dedication of the new mental hygiene bureau of the District of Columbia and welcomed its new director, Dr. John F. Owen.

The annual report of the District Social Hygiene Society recommends revision and strengthening of District health regulations to combat venereal diseases now and during the postwar period.

Optometrists have been added to the "health and welfare services" group of industries considered "essential" to the war effort by the War Manpower Commission. Also included was the manufacture of supplies used by morticians.

Agricultural activity is reported by the Veterans Administration to be among the most valuable forms of occupational therapy for certain types of psychotic patients.

Typical of the national trend, deaths from tuberculosis have declined 10 per hundred thousand of population since 1941, Dr. A. Barklie Coulter, chief of the District health department tuberculosis bureau, reports.

The Census Bureau estimates that 7 out of every 100 babies born in the United States last year were unregistered.

The Foreign Economic Administration reports that 16,000 pounds of amigen, a protein substance, was flown from the United States to prevent death for 80,000 persons in the Netherlands, so near starvation that they cannot digest ordinary food.

Isolation cells of the Industrial Home School for children are comparable to conditions in German "horror camps," according to investigators. Representative John M Coffee, Democrat of Washington, has threatened to send his own investigators to report on conditions in Capital institutions for children.

The District Commissioners have sent to Congress a draft of proposed legislation which would give the District health officer authority to remove and detain by force any recalcitrant carrier of a communicable disease.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Selective Training and Service Act

The House of Representatives has passed H. R. 1812, authorizing the award of a certificate and a medal for faithful service to uncompensated personnel of the Selective Service System who have served for more than two years, including local board examining physicians and dentists and members of medical advisory boards. The medal will be known as the Selective Service Medal.

The Senate Committee on Military Affairs concluded hearings, May 1, on the Ellender bill, S. 637, providing for the deferment of premedical and predental students. Dr. Victor Johnson, Secretary of the Council on Medical Education and Hospitals, and Dr. Harvey B. Stone, a member of that Council, appeared on behalf of the Association in support of the bill. No further action has been taken by the committee.

Medical and Dental Corps

S. 939 and H. R. 3070 have passed respectively the Senate and the House, authorizing the Secretary of War, for the duration of the wars in which the United States is currently engaged and for six months thereafter, to dispense with any part of the examination for promotion in the Regular Army of officers of the Medical, Dental and Veterinary Corps, except those relating to physical examination.

The bill removing the limitation on the right to command of officers of the Dental Corps of the Army which limits such officers to command in that corps, S. 916, has been reported to the Senate by the Committee on Military Affairs with the recommendation that it pass.

Representative Adams, New Hampshire, has introduced, by request, a bill, H. R. 3147, authorizing the appointment of medical technologists as commissioned officers in the Army of the United States and in the Naval Reserve for service with the Medical Department of the Army and of the Navy.

Physically Handicapped Persons

A subcommittee of the House Committee on the Judiciary has ordered favorably reported to the full committee H. J. Res. 23, naming the first week in October as "National Employ the Physically Handicapped Week."

Two recent bills relate to the employment of blind persons. One, S. 987, introduced by Senator Myers, Pennsylvania, proposes to amend the civil service laws of the United States to provide that no person shall be discriminated against in any case because of his or her total or partial blindness in examination, appointment, reappointment, reinstatement, reemployment, promotion, transfer, retransfer, demotion, removal or retirement, unless normal eyesight is absolutely indispensable in the doing of the physical acts to be performed. This bill is pending in the Senate Committee on Civil Service. The other bill, H. R. 3192, introduced by Representative Patrick, Alabama, would encourage and promote the employment of blind persons in public service and in private enterprise by establishing in the United States Employment Service a Division of Blind Placement Agents to stimulate the employment of blind persons.

Veterans Administration

A bill introduced by Senator Downey, California, S. 947, proposes the hospitalization and treatment in Army, Navy and Veterans Administration hospitals of accredited war correspondents who suffer disability as a result of personal injury sustained or illness or disease contracted in the performance of duties outside the continental limits of the United States in time of war.

Two bills, S. 973, introduced by Senator Johnson, Colorado, and H. R. 3115, introduced by Representative Rankin, Mississippi, would liberalize and clarify the laws administered by the Veterans Administration relating to entitlement to domiciliary or hospital care, medical treatment and related services.

Another bill, introduced by Representative Ellsworth, Oregon, H. R. 3166, proposes aid in providing housing for veterans attending educational institutions under the G. I. Bill of Rights.

Representative Bolton, Ohio, has introduced H. R. 3164, to establish the office of adviser to the Administrator of Veterans' Affairs on matters relating to Negro veterans.

S. 974, introduced by Senator Johnson, Colorado, proposes to liberalize and clarify rehabilitation and education and training laws administered by the Veterans Administration. Among other things, this bill would make available under the G. I. Bill of Rights education and training irrespective of whether the education of the veteran was interfered with by entry into service, would make available courses of instruction by correspondence and would increase the amounts payable to veterans undergoing training in pursuance of the rehabilitation program.

Miscellaneous

H. R. 2992 has passed the House extending for a period of one year Public Law 163, 77th Congress, authorizing the Secretary of War and the Secretary of the Navy to establish quarantine boundaries around camps and cantonments and naval bases for the purpose of cooperating with state and local authorities in prohibiting illicit practices calculated to spread venereal diseases. A companion bill, S. 948, is pending in the Senate with a favorable committee report.

A bill introduced by Representative Barry, New York, H. R. 3105, would amend the Federal Trade Commission Act to require publication of facts regarding violations in cases of false advertising of food, drugs, devices and cosmetics. The duty to effect publication will be devolved on the person, partnership or corporation complained of.

Companion bills, S. 962, introduced by Senator Russell, Georgia, for himself and Senator Ellender, Louisiana, and H. R. 3143, introduced by Representative Flannagan, Virginia, propose assistance to the states in the establishment, maintenance, operation and expansion of school lunch programs.

District of Columbia

On April 25 the Senate passed a bill to establish a modern hospital center in the District of Columbia, S. 223. On the following day Senator Ellender entered a motion to reconsider the vote by which the bill was passed, and this motion was considered by the Senate on May 10. After considerable discussion the Senate rejected Senator Ellender's motion to reconsider, and the bill was transmitted to the House of Representatives for further consideration.

Health programs for government employees are proposed by H. R. 2716, which has been reported to the House by the Com-

mittee on Civil Service with a recommendation that it pass. Such health programs, it is contemplated, will be limited to (1) treatment of minor illnesses and dental conditions except in cases of emergency or injury or illness sustained while in the performance of the employee's duty, (2) preemployment and other examinations, (3) referral of employees to private physicians and dentists and (4) education and preventive programs relating to health, including the alleviation of health hazards in the working environment.

The salary of the Executive Secretary, Nurses' Examining Board, District of Columbia, would be increased by a bill that passed the House of Representatives recently, H. R. 2839.

STATE LEGISLATION

Alabama

Bills Introduced.—S. 38 proposes to regulate the manufacture, sale and commercial use of cosmetics and to eliminate from intrastate commerce cosmetics which may be dangerous, injurious or hazardous. S. 12 and H. 116, to amend the narcotic drug act, proposes so to define narcotic drugs as to include isonipecaine. S. 87 proposes to authorize the sexual sterilization of certain socially inadequate inmates of state institutions.

Florida

Bills Introduced.—S. 80 proposes to authorize the establishment of a College of Medicine at the University of Florida. S. 237, to amend the workmen's compensation act, proposes, in effect, to make compensable disability from occupational diseases arising out of and in the course of employment. S. 361, to amend the narcotic drug act, proposes so to define narcotic drugs as to include isonipecaine. H. 400 proposes to require chiropractic licentiates to register annually on or before January 1 with the state board of health and at that time to pay a fee of $1. H. 402 proposes to authorize the establishment of hospital service plan corporations to operate hospital service plans whereby hospital care may be provided at the expense of such corporations to subscribers to such plans by hospitals which have contracts for such care with the corporation.

Illinois

Bill Introduced.—S. 436 proposes to create a commission to investigate the need for developing facilities for the care and treatment of persons who are chronically ill.

Missouri

Bills Introduced.—H. 392 proposes to establish the Southeast Missouri State School for the feebleminded and epileptic. H. 418 proposes to regulate the sale and use of insecticidal or pest control powders containing sodium fluoride, sodium fluosilicate, arsenic or any other poisonous compound. Such substances may be sold only if (1) they are mixed with a coloring substance in sufficient quantity so that the coloring is discernible and (2) the container indicates the poisonous nature of the compound, states the percentage of active ingredient in the mixture and lists one accepted antidote.

Woman's Auxiliary

WINNERS IN THE HYGEIA CONTEST

The American Medical Association offered $400 in cash prizes to the state and county auxiliaries which obtained the largest number of subscription credits to *Hygeia* during the contest, which covered the period from Sept. 1, 1944 to Jan. 31, 1945.

Cash prizes were awarded as follows:

Group 1. Auxiliaries with a membership of 1 to 13:

First prize, $40, to Walla Walla Valley, Wash., Mrs. C. R. Garrett, Hygeia chairman, Walla Walla, Wash.

Second prize, $25, to Cass County, Mo., Mrs. David Long, Hygeia chairman, Harrisonville, Mo.

Third price, $15, to Perry County, Mo., Mrs. J. J. Bredall, Hygeia chairman, Perryville, Mo.

Group 2. Auxiliaries with a membership of 14 to 23:

First prize, $40, to St. Joseph County, Mich., Mrs. A. E. Brunson, Hygeia chairman, Colon, Mich.

Second prize, $25, to Snohomish County, Wash., Mrs. Bernard Berenson, Hygeia chairman, Everett, Wash.

Third prize, $15, to Calhoun County, Ala., Mrs. C. H. Cleveland, Hygeia chairman, Anniston, Ala.

Group 3. Auxiliaries with a membership of 24 to 42:

First prize, $40, to Kitsap County, Wash., Mrs. F. C. Taylor, Hygeia chairman, Bremerton, Wash.

Second prize, $25, to Utah County, Utah, Mrs. W. T. Hasler, Hygeia chairman, Provo, Utah.

Third prize, $15, to Kenosha County, Wis., Mrs. Stephen DeFazio, Hygeia chairman, Kenosha, Wis.

Group 4. Auxiliaries with a membership of 43 to 542:

First prize, $40, to Westmoreland County, Pa., Mrs. A. B. Blackburn, Hygeia chairman, Latrobe, Pa.

Second prize, $25, to Pierce County, Wash., Mrs. J. B. Robertson, Hygeia chairman, Tacoma, Wash.

Third prize, $15, to Buchanan County, Mo., Mrs. C. H. Werner, Hygeia chairman, St. Joseph, Mo.

State winners:

First prize, $40, to state of Washington, Mrs. H. W. Johnson, Hygeia chairman, Everett.

Second prize, $25, to state of Utah, Mrs. Elden Clark, Hygeia chairman, Provo.

Third prize, $15, to state of Missouri, Mrs. D. I. L. Seabaugh, Hygeia chairman, Jackson.

Honorable Mention was given to the following counties:

Prince Georges County, Md., Mrs. Aaron Deitz, chairman, Hyattsville.

Wayne County, Mich., Mrs. W. G. Mackersie, chairman, Detroit.

Jackson County, Mo., Mrs. W. B. Allen, chairman, Kansas City.

Mercer County, Pa., Mrs. John Wassil, chairman, Sharon.

Carbon County, Utah, Mrs. R. W. Robinson, chairman, Kenilworth.

King County, Wash., Mrs. T. T. Robson, chairman, Seattle.

Rock County, Wis., Mrs. H. E. Kasten, chairman, Beloit.

Laramie County, Wyo., Mrs. K. L. McShane, chairman, Cheyenne.

Other counties that have reached or exceeded their quota and had at least 25 subscription credits were Madison County, Ala.; Palm Beach County, Fla.; Richmond County, Ga.; Cook County, Ill.; Rock Island County, Ill.; St. Clair County, Ill.; Sangamon County, Ill.; Vermilion County, Ill.; Cass County, Ind.; Sullivan County, Ind.; Vigo County, Ind.; Dallas-Guthrie counties, Iowa; Dubuque County, Iowa; Central District, Kan.; Saline County, Kan.; Ouachita Parish, La.; Cape Girardeau County, Mo.; Greene County, Mo.; Lafayette County, Mo.; Pettis County, Mo.; Atlantic County, N. J.; Gloucester County, N. J.; Randolph County, N. C.; Stark County, Ohio; Beaver County, Pa.; Blair County, Pa.; Bucks County, Pa.; Lebanon County, Pa.; Mifflin County, Pa.; Venango County, Pa.; Warren County, Pa.; Childress-Collingsworth-Hall counties, Texas; Hunt-Rockwell-Raines counties, Texas; Lamar County, Texas; Liberty-Chambers counties, Texas; Salt Lake County, Utah; Weber County, Utah; Clark County, Wash.; Cowlitz County, Wash.; Spokane County, Wash.; Whatcom County, Wash.; Brown-Kewaunee-Door counties, Wis.; Racine County, Wis.; Washington-Ozaukee counties, Wis.

Other states that reached or exceeded their quotas were Illinois and Wyoming.

This year's contest resulted in 10,894 subscription years as compared to 8,322 subscription years received during last year's contest.

To the state and county Hygeia chairmen, officers and members of the various county and state woman's auxiliaries who have assisted in making this contest a success, Mrs. Arthur I. Edison, national Hygeia chairman, and the circulation manager of *Hygeia* express appreciation.

Bureau of Information

INFORMATION FROM FOURTEEN REPRESENTATIVE COUNTIES IN ILLINOIS

The first summary sheets from counties containing very large cities have been received from the Illinois State Medical Society through its executive secretary, Dr. Harold M. Camp.

The accompanying table gives some of the economic features of fourteen representative counties in Illinois, including rural areas and the large urban area of Chicago.

Economic Features of Fourteen Counties in Illinois

County[1]	Principal Cities[2]	Population	Physicians Under 65	Persons per Physician	Persons per Telephone[3]
Bond		13,025	4	3,256	8.6
	Greenville	3,391			
Cook		3,968,320	3,245	1,223	5.8
	Chicago	3,396,808			
	Oak Park	66,015			
	Evanston	65,389			
Cumberland		9,466	2	4,733	11.9
Fayette		23,351	7	3,336	10.4
	Vandalia	5,288			
Grundy		18,282	9	2,031	8.6
	Morris	6,145			
Jasper		10,872	1	10,872	13.7
	Newton	2,347			
Jersey		12,667	4	3,167	12.7
	Jerseyville	4,899			
Jo Daviess		19,529	9	2,181	7.2
	Galena	4,126			
Lee		32,237	11	2,931	6.7
	Dixon	10,971			
Macon		84,638	54	1,567	8.3
	Decatur	59,305			
Pike		20,927	4	5,232	8.5
	Pittsfield	2,884			
Pope		5,668	2	2,834	9.6
Sangamon		113,393	63	1,800	7.5
	Springfield	75,503			
Winnebago		126,110	88	1,433	9.2
	Rockford	84,637			

1. Bureau of census, estimated population 1943.
2. Bureau of census, population 1940.
3. Based on 1940 figures, American Telephone and Telegraph Company.

Excerpts from the remarks contained on some of the county summary sheets follow:

Lee.—Two or three towns in this county of 600 to 800 population, 12 to 15 miles from a hospital, have one or no doctors.

Macon.—Men now in service plan to return here after the war. In addition there are fifteen to twenty younger men who have never practiced that plan to come back to this, their home town, to practice.

Pike.—Better than average facilities for practice in a county of this size.

Sangamon.—All doctors now in service from this county plan to return. The present prosperity is largely due to war work. After the war this will be a poor location for new doctors, as about fifteen local boys who have not practiced expect to locate here.

Winnebago.—If a maximum of 50 per cent of the doctors who practiced in this community and who are now in the armed forces return to practice here after the war, the medical facilities will be adequate.

Included with the Illinois summary sheets was a list of towns in the state that are now in need of physicians. Many of these communities have good opportunities for physicians desirous of a locality in which to establish a practice. Inquiries from veteran medical officers about these and other areas will be answered so that interested officers will be given helpful information and be referred to the local medical societies concerned for further investigation. Since vacancies are being held open in many communities for doctors now in military service, direct correspondence with the county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Official Notes

REGISTRATION UNDER THE HARRISON NARCOTIC ACT

A Reminder from the Bureau of Legal Medicine

Physicians, other than those in the armed services, who are registered under the Harrison Narcotic Act or under the Marihuana Tax Act must effect registration on or before July 1 to avoid a penalty. Each year, despite the annual warnings in THE JOURNAL, this requirement is overlooked by some physicians and unpleasant consequences follow. Failure to register adds a penalty of 25 per cent to the tax payable and in addition subjects the physician to the possibility of a fine not exceeding $2,000 or to imprisonment for not exceeding five years, or to both. As an act of grace the Commissioner of Internal Revenue has in past years given some tardy registrants the choice between paying sums by way of compromise, a procedure authorized by law, or of accepting criminal prosecution. If this procedure does not produce the required promptness in reregistration, the commissioner will have no other alternative than to institute criminal prosecution.

A physician in the armed forces need not reregister. If he receives an application form for reregistration, it should be returned to the office of the Collector of Internal Revenue together with a statement showing that he is in service and requesting that the registration number previously assigned to him be reserved. A physician on entering service should return all unused order forms to the collector's office and should dispose of all narcotics or cannabis on hand either by returning them to the wholesale concern from which purchased, if the packages are in unbroken form, or by transferring the narcotics or cannabis to another physician after having obtained permission for such transfer from the office of the Collector of Internal Revenue.

A physician entering service also is required to return the special tax stamp to the collector, who will mark the stamp "Business Discontinued" with the date and return the stamp to the physician to be retained in his files for a period of not less than two years. When a physician is discharged from military service and reengages in civilian practice during the same fiscal year for which his registration has been canceled he will not be required to secure another stamp and pay a second tax for the remainder of that fiscal year. Such a physician should notify the office of the Collector of Internal Revenue, within thirty days of resuming practice, of his intentions to reenter the private practice of medicine. He should return the special stamp retained in his files to the collector so that the notation "Business Discontinued" may be crossed out and a proper notation made on it, indicating that private practice has been resumed.

DOCTORS LOOK AHEAD

First topics for the next several weeks of the radio series Doctors Look Ahead are as follows:

May 19. Look Sharp.
May 26. Unfinished Business; speaker, Morris Fishbein, Editor, THE JOURNAL.
June 2. Fit to Live: an appraisal of the nation's health and of its fitness for war and for the peace to come.
June 9. They Shall Hear Again: a program devoted to the interests of all those with hearing defects; speaker, Howard A. Carter, Secretary of the American Medical Association Council on Physical Medicine.
June 16. American Spas; speaker, Walter S. McClellan, New York.

Some stations may record the program and broadcast it at a time which suits their schedule better. Local newspaper radio announcements should be consulted.

It is sometimes necessary to cancel or postpone certain programs because of unforeseen developments due to world events.

When no speaker is announced the summary will be given by Dr. W. W. Bauer, Director of the Bureau of Health Education. Doctors Look Ahead is heard on one hundred and twenty-three stations of the National Broadcasting company network each Saturday at 4 p. m. Eastern War Time (3 p. m. Central War Time, 2 p. m. Mountain War Time and 1 p. m. Pacific War Time).

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

COLORADO

Refresher Course in Rheumatic Fever.—The University of Colorado School of Medicine, Denver, will conduct a three day refresher course on rheumatic fever June 4-6. The subject will be presented from the standpoint of incidence, epidemiology, diagnosis, treatment and prophylaxis. Presentation of the subject material, much of which will be made available through the Denver Area Rheumatic Fever Diagnostic Service, will involve demonstration clinics and well illustrated lectures. Through the courtesy of the Public Service Company of Colorado an electric stethoscope with loud speaking amplification will be available for the clinical demonstration of heart sounds.

CONNECTICUT

Society News.—Dr. Vladimir Lebedenko, representative in the United States of the Mission of Alliance of Red Cross and Red Crescent Societies of the Soviet Union in the United States, addressed the Yale Medical Society, New Haven, April 11, on "Organization of Russian Medicine in Wartime."

Personal.—Charles-Edward Amory Winslow, Dr.P.H., New Haven, will make a survey of health and hospital facilities in the Washington metropolitan area for the Metropolitan Health Council of Washington, according to *Science*.——Dr. Stanley H. Osborn, Hartford, state health officer, recently was awarded the honorary degree of doctor of public health by Trinity College, Hartford.

DISTRICT OF COLUMBIA

Personal.—Lieut. Col. Leo V. Schneider, M. C., associate clinical professor of medicine, Georgetown University School of Medicine, and chief medical officer of Glenn Dale Sanatorium, Glenn Dale, Md., has been made chief of industrial medicine, New York Port of Embarkation.

Borderline Certificates Continued.—In accordance with action at a recent meeting of the representatives of the Commission on Licensure of the District of Columbia and the Board of Medical Examiners of Maryland, the latter rescinded its action concerning the approval of borderline certificates and voted to continue issuing the certificates for the duration of the war (THE JOURNAL, Dec. 16, 1944, p. 1039).

Captain Newhouser Gives Kober Lecture.—The 1945 Kober Foundation lecture was delivered by Capt. Lloyd R. Newhouser (MC) on "The Role of Whole Blood Plasma and Plasma Fractions in War Medicine." The lecture was given March 28, the birth date of the late Dr. George M. Kober, for many years dean of the Georgetown University School of Medicine and founder of the lecture. Captain Newhouser was presented with an honorarium of $500 by Lawrence C. Gorman, S.J., president of Georgetown University, who stated that the selection had been made this year by the Association of Military Surgeons of the United States. Vice Admiral Ross T. McIntire, Surgeon General of the Navy, presided.

John Owen Named to New Bureau.—Dr. John F. Owen, superintendent of the State Hospital, Raleigh, N. C., has been appointed in charge of the new mental hygiene bureau in the health department of the District of Columbia. Under the supervision of Dr. George C. Ruhland, health officer, he will develop a program of mental hygiene in the District to include the establishment of clinics for school and preschool children, children involved with the Juvenile Court and Detention Home, alcoholic and drug addicts, adults accused of antisocial behavior and patients now in St. Elizabeths Hospital who need only psychiatric supervision. The *Medical Annals of the District of Columbia* states that the project will be financed by an appropriation of $24,340.

GEORGIA

University to Construct Hospital for Indigent.—The Georgia Legislature recently enacted a bill authorizing the board of regents of the University System of Georgia to construct and operate a hospital for the indigent sick and near indigent sick in conjunction with the University of Georgia School of Medicine, Augusta.

Coordinator of Health Education.—Mr. J. M. Gooden, formerly state school supervisor, has been chosen state coordinator of health education to inaugurate a program to coordinate and utilize all available services of the state which can contribute to the promotion of better health among Georgians. Mr. Gooden was chosen by a joint committee from the Georgia Department of Public Health, the state department of education and the University System of Georgia. The program will be confined principally in the beginning to a few selected countries where an intensive health program will be developed in the schools and communities, according to *Georgia's Health*. A grant from the W. K. Kellogg Foundation, Battle Creek, Mich., is financing the project. Mr. Gooden's headquarters are with the Georgia Department of Public Health, Atlanta 3.

IOWA

State Medical Election.—Dr. Robert L. Parker, Des Moines, was chosen president-elect of the Iowa State Medical Society at its meeting in April. Dr. Ransom D. Bernard, Clarion, was installed as president. Dr. John C. Parsons, Des Moines, is secretary and Miss Mary L. McCord, Des Moines, executive secretary. The 1946 meeting will be held in Des Moines, the tentative dates having been set as April 17-19.

Tropical Diseases.—The State University of Iowa College of Medicine, Iowa City, and the state department of health, in cooperation with the U. S. Public Health Service, will conduct a special laboratory course in malaria and other tropical diseases at the state hygienic laboratory, Iowa City, July 23-28. The instructors will be Dr. Milford E. Barnes, professor of hygiene and preventive medicine, and Kenneth MacDonald, Ph.D., assistant professor, both of the college of medicine, and Dr. Irving H. Borts, director of the state hygienic laboratory.

KANSAS

University News.—Mrs. Logan Clendening, Kansas City, Mo., has been appointed by the chancellor of the University of Kansas to be the curator of the library of medical history, which was endowed in the will of the late Dr. Clendening (THE JOURNAL, April 7, p. 934).——The plan to establish a memorial fund in honor of the late Dr. Clarence B. Francisco, Kansas City, Mo. (THE JOURNAL, April 15, 1944, p. 1142), has considerably enlarged into a campaign for a student union building including a dormitory, gymnasium and cafeteria, a special lounging room in the building and library to be set aside as a memorial to Dr. Francisco. According to the *Journal of the Kansas Medical Society* $43,000 of the proposed cost of $300,000 has been subscribed.——Paul G. Roofe, Ph.D., assistant professor of anatomy, University of Louisville School of Medicine, has been appointed professor of anatomy and chairman of the department of anatomy, University of Kansas School of Medicine, effective September 1. ——The recent legislature provided for $350,000 for a new surgical building at the medical school, referred to as a connecting corridor, which will add 70 to 90 beds to the hospital.

NEBRASKA

Personal.—Dr. Chauncey M. Pierce was recently elected president of the Chadron chamber of commerce.——Dr. Leland C. Albertson has resigned as medical director of the Hospital for the Tuberculous, Kearney, effective May 1. Dr. Albertson has been associated with the hospital since 1934 and has served as director since 1940.

Prepayment Sickness Insurance.—The Nebraska State Medical Association has approved the Nebraska Surgical Plan for nonprofit prepayment sickness insurance benefits. The plan, which has been in operation in Douglas County since Nov. 1, 1944, will be integrated with the Blue Cross, which for a small fee pays subscribers' hospital bills within certain limitations. The surgical plan offers subscribers, for a monthly fee, surgical, maternity, x-ray, pathologic and anesthesia benefits. It also provides for treatment of certain minor surgical cases in the physician's office, such as fracture of the wrist, minor lacerations or incision of a boil. It does not cover medical service, such as house visits in the case of ordinary illness for conditions such as infectious diseases, influenza, pneumonia or other medical afflictions. When sufficient experience has been accumulated, benefits for treatment of medical cases confined within a hospital will be added to the surgical-maternity benefits. The benefits now offered would be available to all immediate members of a family for only $2 a month. Without maternity benefits an individual's assessment would be 75 cents a month, and an individual with one dependent

would pay $1.50 a month. To insure a fair cross section of subscribers, the surgical plan, like Blue Cross, is offered only on a group basis. In rural areas it is proposed to enroll farm groups through project clubs, townships, school districts and such cooperative groups as the Farmers Union. The members of the planning committee of the state association which proposed the plan to the association after a year's study are Drs. Floyd L. Rogers, Lincoln, chairman; Albert L. Cooper, Scottsbluff; Morris Nielsen, Blair; Donald B. Steenburg, Aurora, and Arthur J. Offerman, Omaha. The business administration of both the Nebraska Surgical Plan and the Blue Cross will be in charge of J. H. Pfeiffer, Omaha, executive director. Each plan, however, will have its own board of directors.

NEW HAMPSHIRE

New Roentgen Ray Society. — The New Hampshire Roentgen Ray Society was recently organized with Dr. Fred S. Eveleth, Concord, president, and Dr. Richard C. Batt, Berlin, secretary-treasurer. The aim of the society is to maintain and improve radiologic service in the state and to promote cooperation between clinicians, radiologists and hospitals.

NEW YORK

Need of Diagnostic Clinics Studied. — The Medical Society of the State of New York is conducting a survey to determine the need for diagnostic aid centers. The study is being directed by the society's subcommittee on laboratory service and medical care.

New York City

University News.—Dr. John J. H. Keating, 1917 graduate, was chosen president of the Association of the Alumni of the Columbia University College of Physicians and Surgeons at its annual dinner April 21. Other officers include Drs. Bernard S. Oppenheimer, class of 1901, vice president; James A. Corscaden, class of 1906, treasurer; Charles C. Lieb, class of 1906, secretary, and T. Lloyd Tyson, class of 1931, historian.

New Orthopedic Fellowship.—The Mr. and Mrs. Frederick Brown Orthopedic Research Fellowship has been created at the Hospital for Joint Diseases by Mr. Frederick Brown, president of the hospital, with an initial gift of $7,500 on the occasion of his seventy-fifth birthday. Immediately after the war and as soon as young physicians return from military service, the hospital will begin awarding the research fellowship to carefully selected candidates to be nominated by a committee on awards consisting of Mr. Brown, Mr. Max Wilner, chairman of the board; Mr. L. F. Rothschild, treasurer; Dr. Abraham J. Beller, president of the medical advisory board; Dr. Henry L. Jaffe, director of laboratories, and Dr. Jacob J. Golub, medical director of the hospital. Under the terms of the fellowship the recipients of the awards will be chosen without regard to race, creed or color. Applicants must be graduates of approved medical schools and must have completed previous internships and approved residencies. The selection will be made on a merit basis, the qualifications being essentially scholarship, previous training and research tendencies.

Nutrition Clinic Established.—A city-wide nutrition clinic has been established at the lower East Side Health and Teaching Center with Dr. Norman H. Jolliffe as chief of clinic, according to Dr. Frank A. Calderone, acting city commissioner of health. Objectives of the clinic are:

To furnish a diagnostic and treatment center and consultation clinic for patients suspected of having nutritional abnormalities.
To furnish a training center for physicians, nurses and others interested in the diagnosis, treatment and prevention of deficiency diseases.
To develop and correlate diagnostic methods for the detection of early nutritional diseases.
To determine the significance of various manifestations of nutritional diseases.
To determine the most effective methods of treatment and prevention of deficiency diseases.
To obtain information concerning food habits in relation to nutritional disease.
To translate, when indicated, the diagnostic procedures and conclusions of this clinic into practice in other health department units.

Plans are being formulated for the Public Health Research Institute and the nutrition division of the department of health to cooperate with the nutrition clinic so that it will be possible to correlate the dietary and chemical studies with the medical findings.

Gifts to Long Island College of Medicine.—Gifts and grants totaling $127,374.15 were made to the Long Island College of Medicine, Brooklyn, in the year ended January 1 for nine research projects, new college laboratory facilities, scholarships, student aid and a library for the new William Alanson White Clinic. Contributions through the development fund still in progress comprised the largest single item on the report, with a total in gifts secured up to January 1 of $63,784.05. This fund was used to provide new laboratories for the departments of medicine, anatomy, biochemistry and radiology, for which extensive structural alterations have been made in the Polhemus Memorial Building at 350 Henry Street, the Hoagland Laboratory Building at 335 Henry Street and the Polak Laboratory at 123 Pacific Street. The second largest item was a continuation of the six year grant from the Commonwealth Fund, which gave $16,890.83 for the development of the college's new department of psychiatry, which is located in a new building at 88 Amity Street and named after the late Dr. William Alanson White, graduate of the college in the class of 1891, who was director of St. Elizabeths Hospital, Washington, D. C. The initial grant of $5,112.50 for this department was made in 1943. An anonymous contribution of $2,500 was made for the library of this new psychiatric clinic. Another anonymous contribution of $4,900 was made to install new laboratory and library facilities in the college division at Kings County Hospital. When completed this whole project will cost $10,000, with the remainder to come out of development fund contributions. A new endowed scholarship amounting to $5,350 was established in the name of Mrs. Sarah Beinfield Messing, whose son is a graduate of the college and whose grandson is a member of the present senior class. A new prize award was established in 1944 by the late Mrs. Joseph Howard Raymond with a gift of $995 in memory of the late Dr. Joseph Howard Raymond, secretary of the faculty from 1888 to 1915 and professor of physiology from 1873 to 1915.

OHIO

University News.—The Commonwealth Fund has appropriated $8,200 to be used by Dr. Carl J. Wiggers and associates of the department of physiology, Western Reserve University School of Medicine, Cleveland, to continue their studies on the peripheral circulation and shock during 1945-1946.

Graduate Assembly.—The seventeenth annual postgraduate assembly of the Mahoning County Medical Society was conducted at the Pick-Ohio Hotel, Youngstown, April 11, among others, by members of the faculty of Marquette University School of Medicine, Milwaukee. The speakers included:

Dr. Frederick W. Madison, Present Trends in Hemorrhagic Diseases.
Dr. Carl W. Eberbach, Treatment of Biliary Tract Diseases.
Dr. Francis D. Murphy, Diagnosis and Treatment of Nephritis.
Dr. Eben James Carey, The Future of Medicine.

Narcotic Ring Exposed.—On March 30 a $100,000 a year "dope racket" in the Akron area was exposed by federal narcotic agents, according to the Akron *Beacon Journal*. The so-called ring is said to involve 150 addicts. The seven persons arrested included two physicians, Drs. Erich Otten and Roy T. Haskell, both of whom were charged with the "sale of narcotics," pleaded not guilty and were freed under $1,500 bond. Dr. Haskell is reported to have written drug prescriptions in the name of a patient, now dead, and continued to obtain drugs in that patient's name.

Personal.—Dr. Howard Dittrick was reelected president of the Cleveland Medical Library Association at its recent meeting. Dr. Dittrick is also director of the association's museum. Dr. Justin A. Garvin was elected secretary.——Drs. Robert H. Bishop Jr., director of the University Hospitals, and Henry J. Gerstenberger, director of pediatrics, Babies and Childrens Hospital, Cleveland, were given diplomas recently from the Hospital Infantil, Mexico City, in recognition of their work in training physicians and nurses from Mexico City.——Dr. Arthur D. Blackburn, Circleville, health commissioner of Pickaway County, has been elected vice president of the United Roller Club of America, an organization which promotes interest in roller pigeons.——Dr. William Edward Blair, Lebanon, who has completed twenty-five years as health commissioner of Warren County, has been reappointed for an additional two year term.——Dr. Edwin J. Cauffield, Akron, completed fifty years in the practice of medicine, March 25.

TENNESSEE

Enjoined from "Practicing" in Florida—Runs Clinic in Tennessee. — William Estep, who was enjoined from the practice of medicine in what was known in Pensacola, Fla., as a Vita-Ray Clinic, has opened the "Memphis Research Clinic" and was on April 12 advertising the institution as an "x-ray clinic for chronic diseases," according to the Memphis *Commercial Appeal*. It was stated that the injunction restraining Estep from practicing medicine in Florida was decreed last December 4 by Judge Ernest E. Mason of the Escambia County, Fla., Court of Record. The case is now pending before the Florida Supreme Court on appeal, it was stated.

Estep is said to have recorded a license as a naturopathic physician. Dr. Harley W. Qualls, secretary of the Tennessee State Board of Medical Examiners, is reported to have said that there is no doctor with the name William Estep in any state in the United States licensed to practice medicine. On warning by the secretary of the state board that as a naturopathic physician he was not entitled to use x-rays, Estep is supposed to have said that his attorney had told him it was permissible. Dr. Qualls, in a statement to the press, said that he visited the clinic and was surprised to learn, following his examination by Estep, that he had high blood pressure, sinus trouble caused by "pus pockets," and six stomach ulcers. In addition to what Estep said were "vita-ray" and "electromagnetic" treatments for the sinus and ulcers, Dr. Qualls was given prescriptions for drugs to take for each ailment. The Florida State Board of Medical Examiners revoked Estep's license, Nov. 23, 1942 on the grounds that it had been obtained fraudulently from the late Dr. George A. Munch, secretary of the old Eclectic Board, who served a sentence in federal prison for using the mail to defraud.

VERMONT

University News.—Dr. Harold E. Himwich, professor of physiology and pharmacology at Albany Medical College, recently addressed the Osler Clinical Society, the student's organization at the University of Vermont College of Medicine, Burlington, on "Hypoglycemia, Its Physiology, Pathology, Symptoms and Treatment." Capt. Arthur E. MacNeill, M. C., also spoke before the society recently on "The Work of an Army Air Force Flight Surgeon." Dr. John F. McIntosh, secretary to the McGill University Faculty of Medicine, Montreal, Quebec, addressed the society April 4 on the problem of urinary calculi in ancient times and in a modern clinic.

WASHINGTON

Dean Now Sought for New Medical School.—One of the first steps toward the creation of the University of Washington Medical-Dental School will be the selection of a dean who will be the adviser and director of future developments. The school will be confined to teaching the basic sciences of anatomy, physiology, chemistry, pathology and bacteriology, subjects already established in the premedical courses (THE JOURNAL, April 21, p. 1067).

WEST VIRGINIA

Hospital News.—The state legislature has passed a bill designating the state health department as the sole state agency to deal with the federal government concerning a bill pending in Congress appropriating one million dollars for postwar hospital construction and five million dollars to finance state surveys of hospital needs. The bill in the state legislature authorizes the governor to appoint an advisory committee to consult with the state health department in all matters concerned with the new project. The Barboursville unit of the Weston State Hospital (mental), Weston, will hereafter be known as the Barboursville unit of the Huntington State Hospital, Huntington, in accordance with a recently passed bill.

GENERAL

Actions on 1945 Conventions.—Reports received by the American Medical Association indicate the following action for the 1945 sessions of the respective organizations:

American Ophthalmological Society, canceled.
Maine Medical Association, canceled.
Utah State Medical Association, canceled.

Dr. McQuarrie Named Editor of Brennemann's Practice of Pediatrics.—Dr. Irvine McQuarrie, professor and head of the department of pediatrics, University of Minnesota Medical School, Minneapolis, has been appointed editor of Brennemann's Practice of Pediatrics, published by W. F. Prior Company, medical publishers, Hagerstown, Md.

Facts About Tuberculosis.—The United States Public Health Service has made available a second presentation in graphic form of the statistics regarding tuberculosis in the United States. It is devoted to proportionate mortality statistics for the states in geographic divisions. Deaths are classified according to age, sex and race and are comparative for the last three decades.

Research Council to Act as Adviser to Cancer Society.—The National Research Council has agreed to act as adviser to the American Cancer Society in its proposed comprehensive research program on the entire cancer problem. About one third of the five million dollars now being sought in the society's campaign for funds is to be devoted to cancer research. The role of adviser will be carried out through the division on medical sciences of the National Research Council, which will establish a committee on growth of fifteen members.

Medical Advisory Committee Named for Compensation Commission.—A medical advisory committee has been appointed to the United States Employees' Compensation Commission to advise on special medical problems incident to the handling of cases of silicosis reported under the federal workmen's compensation laws. Members of the committee include Dr. Royd R. Sayers, director of the Bureau of Mines, U. S. Department of the Interior, Washington, D. C.; Dr. Leroy U. Gardner, Saranac Lake, N. Y.; Lieut. Col. Anthony J. Lanza, M. C., and Dr. Clarence D. Selby, Detroit. The first meeting was held May 10 in New York.

Biometrics.—The American Statistical Association has recently brought out a *Biometrics Bulletin*, official organ of the biometrics section of the association. It is designed primarily for biologists who see in statistics a potent tool for their work and will be developed to meet the needs of the membership. The biometrics section of the American Statistical Association was established in 1938. The first issue includes a discussion of the new bulletin, an article on "Some Uses of Statistical Methods in Medicine" by John R. Miner, Sc.D., Rochester, Minn., abstracts, queries and news items. The new bulletin will be published six times a year by the association, 1603 K Street N.W., Washington 6, D. C. Material for the bulletin should be sent to Gertrude M. Cox, M.S., chairman of the editorial committee, North Carolina State College, Raleigh, N. C.

Improvement in Cancer Control.—Noticeable progress has been made in combating cancer, particularly among women, according to the statisticians of the Metropolitan Life Insurance Company. Among the insured white females aged 1 to 74 years the standardized cancer death rate dropped as much as 11 per cent in the decade 1934 to 1944, and even for the preceding quarter of a century the death rate from this cause stayed fairly stable or showed a downward trend for women in every age group below 65 years. "The net result of these developments," the statisticians say, "has been to bring the current death rates from cancer among the white women in the broad age of 25 to 64 years to the lowest levels on record in this third of a century of insurance experience; it is a striking fact that in the ages 35 to 54 the mortality dropped one fifth between 1911-1913 and 1942-1944. Even among white male policyholders the situation has shown slight improvement in recent years. The distinctly upward trend in the mortality from cancer which was manifest during the first quarter century of this insurance experience has been stemmed, if not reversed. During the past decade, at no age period beyond 25 years has the cancer death rate among these insured men increased; in fact, it appears that at some age periods the mortality has tended downward recently." The gain in the control of cancer mortality is attributed by the statisticians to a number of factors. Among these are the organized movement for such control, which has caused people to seek diagnosis and treatment earlier in the course of the disease, prevention of the disease itself by more attention to personal hygiene, and in women through better obstetric and postpartum care. Added to these factors aiding in the control of cancer are the constantly increasing number of physicians trained to deal effectively with the disease, the increase in the public and private facilities for the treatment of cases and the development of new and improved technics. Significant this year, the statisticians point out, is the fact that 1945 not only marks the one hundredth anniversary of the birth of Wilhelm Konrad Roentgen, born March 27, 1845, but also the fiftieth anniversary of his discovery of the x-rays, "which have proved invaluable in the diagnosis and treatment of cancer as well as of many other diseases."

PUERTO RICO

Legislation Affecting Pharmacy.—Under a bill passed by the legislature of Puerto Rico and waiting the governor's signature, the Board of Pharmacy of Puerto Rico would have the power to regulate the practice of pharmacy. Under the bill the "assistant pharmacists," or "practical pharmacists" as they are called in Puerto Rico, would have legal recognition but would be subject to legal regulation, and they would be required to perform their work under the supervision of registered pharmacists all the time.

Proposed Health Grants.—According to Dr. Antonio Fernos Isern, San Juan, commissioner of health of Puerto Rico, an appropriation of about $2,000,000 from federal funds will be given Puerto Rico for different health projects during

the fiscal year 1945-1946. The money would come from part of the $100,000,000 appropriation bill now pending in Congress for health and sanitation work in the states and territories, according to an announcement. Priorities have been obtained for the construction of twenty-five additional health units in Puerto Rico, for which the legislature appropriated funds recently. Dr. Fernos Isern stated that the federal money would be used for the construction of hospitals and public health centers to fight malaria, tuberculosis and venereal diseases in the island.

FOREIGN

The Harveian Lecture.—Sir Alexander Hood, director-general of the Army Medical Services will deliver the Harveian lecture at the Royal College of Surgeons, England, May 28. His subject will be "Total Medicine."

Treatment Centers for Rheumatism.—The British Empire Rheumatism Council plans to cooperate in the establishment in Britain of a national chain of treatment centers to enable comprehensive tests under full control conditions to be made for evaluating present and proposed new means of treatment of rheumatism.

Appointment to New Chair of Industrial Health.—Dr. Ronald E. Lane, who has been lecturer in factory hygiene and lecturer in medicine at the University of Manchester, has been appointed to a new chair of industrial health, which was created recently by the Nuffield Foundation under a grant of £70,000. According to *Science* Dr. Lane is expected to take up his new work next September.

Personal.—Dr. James Mackintosh, dean of the London School of Hygiene and Tropical Medicine, has been lecturing in Sweden for the British Council on "Housing and Medicine" and "Nutrition and Medicine."——Dr. H. A. Krebs, who graduated in medicine at the University of Hamburg in 1925, has been appointed to the newly established chair of biochemistry in the University of Sheffield, Yorkshire, England, where some years ago he, as lecturer, founded a school of biochemical research which has received support from the Medical Research Council and the Rockefeller Foundation.

First Health Inspector General Named for South Pacific.—Dr. John C. R. Buchanan, formerly deputy director for medical services in Uganda, has been named the first health inspector general of the South Pacific in line with a new plan to create a Pacific public health service planned by the British Empire. According to the New York *Times* the decision to adopt the plan, which envisages joint public health and medical services for Fiji, the British western Pacific territories and New Zealand Island territories in Oceania was made in conjunction with London and Wellington. It followed an investigation of existing services in Fiji by New Zealand officials. The headquarters of the setup will be located in Suva Fiji, which is conveniently situated for training the necessary personnel and for expansion.

Growing of Herbs in Russia.—One hundred thousand acres on ten thousand collective farms in Russia are planted to medicinal herbs, and in the near future thirty new stations of the All-Union Medicinal Trust will begin gathering wild herbs and assisting in their cultivation on collective farms, as well as in their processing, the Russian Information Bureau reports, as published in the New York *Times*. Eight thousand tons of herbs was gathered in 1944 by the trust. Each summer groups of botanists explore all parts of the country to find new varieties. An expedition to the Tian-Shan mountains discovered vast growths of termopsis, the seeds of which are used in the production of medicines for treatment of ailments of the respiratory tract. From the Turkmenian desert came a plant from which salsolin, used for lowering blood pressure, is obtained, it was stated.

Joint OSE Medical Mission to Yugoslavia.—The Union of OSE, Geneva, cabled the OSE in New York City through the United States Legation in Bern on April 4:

> Joint OSE Medicosocial Relief Mission consisting of 6 physicians and 8 other staff members along with 7 tons of supplies, medical and restorative, left Switzerland March 17 for Yugoslavia via Marseilles. Its aim is emergency relief to displaced persons, particularly Jews liberated from camps and diffused throughout newly liberated territories. Received cabled news that our previous mission, consisting of 6 persons, left Naples for Hungary accompanied by American Jewish Joint Distribution Committee delegate Israel Jacobsohn. Joint OSE Polish Mission has now been provided with necessary supplies, is ready to start and is expecting visas shortly.

According to the information of the American Jewish Joint Distribution Committee its representative, Mr Jacobsohn, went to Yugoslavia. Whether he will join the mission to Hungary and whether that mission will gain admission is still problematic.

Health Campaign in Sweden.—The Medical Association of Sweden and the Swedish Gymnastics League are sponsoring a general health campaign throughout the country. Physicians are giving lectures and demonstrations, and educational printed material is being distributed. Health weeks will be observed. On the initiative of the head of the new School Hygienics Bureau Dr. Carl W. Herlitz, Stockholm, Sweden, has adopted a uniform system of health registration in the schools. It is hoped to tie up this registration at school with the health registration of the Swedish conscripts. About $150,000,000 a year is expended in the treatment for diseases alone. In addition, losses in working hours and productive capacity cost about $250,000,000. This information is revealed in a recent survey by Dr. Sven Rydenfelt, Lund University, during the years 1940 and 1941. The bulk of these costs is paid by the state in the form of costs for public health and the care of the sick, benefit funds and invalidity relief. The remainder may be regarded as social-economic expenditure disbursed by the citizens, for example, for dental and medical treatment, medicine and payments to sick benefit funds, according to the Swedish International Press Bureau.

Air Ambulance Pilot Honored.—An air ambulance pilot of the Royal Swedish Air Force, Sergeant Major Allan Norberg, was recently awarded the prize for the most noteworthy Swedish flying feat of the year, instituted by the newspaper *Stockholms-Tidningen* and consisting of a gold medal and a grant of money. During a 950 kilometer flight to a remote place in the mountainous wilds of Lapland in order to save two Norwegian refugees, Sergeant Major Norberg was forced by bad weather to fly not more than 300 feet over the treetops. For seven years Norberg has been active as an air ambulance pilot, and during 1944 he transported in all 164 persons from isolated parts of Lapland to hospitals in the coastal towns, often under the severe weather conditions of arctic cold and heavy snowstorms. The Swedish air ambulance service was started in 1923 with support by the state and the Swedish Red Cross. It is now incorporated in the Swedish air force, which places aircraft and personnel at disposal. The ambulance planes are stationed at three airports in northern and central Sweden: at Boden, just below the arctic circle, at Östersund in the province of Jemtland, and at Hägernäs in the Stockholm archipelago. During the war years planes especially from the first mentioned station have been engaged in rescuing refugees who have crossed the border in northernmost Sweden.

CORRECTION

Minutes of Board of Trustees.—In the fourth line of the third paragraph, under "Appointments," in the abstract of minutes of the meeting of the Board of Trustees held Feb. 15 and 16, 1945 (THE JOURNAL, March 24, p. 719), "American Pediatric Society" should read "American Academy of Pediatrics."

Government Services

Industrial Hygiene Division Moves

On April 6 the outlying offices of the industrial hygiene division of the U. S. Public Health Service moved into building three of the National Institute of Health, Bethesda, Md. According to the Industrial Hygiene *News Letter* the move brings the entire division, with the exception of the chemical unit, in one building.

Consultant Services Extended by Industrial Hygiene Division

Dr. Walter E. Doyle, Surgeon (R), chief of the industrial hygiene division of the U. S. Public Health Service, recently completed the first of a series of tours planned in a program of extending the consultative services to the states. The first tour was carried on in U. S. Public Health Service District number 7, comprising the industrial hygiene units of Minnesota, Iowa, Missouri, Arkansas, Oklahoma and Kansas. According to *Industrial Medicine*, Dr. Doyle plans to visit every state and every local industrial hygiene unit in the state and in the nation. He is making the annual evaluation conducted by the industrial hygiene division in the units he visits, although major emphasis is placed on giving aid in the medical control of occupational disease.

Foreign Letters

LONDON

(From Our Regular Correspondent)

April 14, 1945.

Postgraduate Training of Medical Officers on Release from the Forces

The government recognizes that many medical officers who joined the armed forces during the war were unable to complete the postgraduate training usually received before entering into civilian practice and that others have had their normal professional experience interrupted or curtailed in certain respects over a period of years. The government thinks that every opportunity should be given to medical officers when released from the forces to continue their training or to bring down to date their professional knowledge in those branches of medicine required in civilian practice. Accordingly, after consultation between the Ministry of Health, the universities and other interested bodies, arrangements are being made by which officers on release will avail themselves of further training or refresher facilities.

The following are the classes of officers concerned: 1. Those who joined the forces within a year or so of obtaining a medical qualification, including those who would have proceeded further to take a university medical degree but were prevented by recruitment from doing so. 2. Those who had become established in general practice before joining the forces. 3. Those who were training for a specialist career when they joined the forces or are accepted as suitable for such training on release. Class 1 will be offered salaried resident posts for up to six months at teaching hospitals or other hospitals approved by the universities, where they will have access to suitable clinical material and work under the guidance of senior members of the visiting staffs. For class 2 refresher courses will be arranged at hospitals approved by the universities. For class 3 there will be posts of the "registrar" type in teaching and other hospitals approved by the universities, where they can continue their specialist training.

The posts available to class 1 will carry a salary of $1,750 plus board and lodging. For those with family commitments further assistance will be available. The refresher courses for class 2 will be free of cost. Traveling and subsistence expenses, together with the expense of a locum tenens when necessary, will be repayable up to a specified maximum. The posts available for class 3 will carry a salary of $2,750 plus board and lodging.

Typhus Causes a Truce

By negotiations between British and German officers, British troops took over from the S. S. and the Wehrmacht the task of guarding the vast concentration camp at Belsen, a few miles northwest of Celle, which contains 60,000 prisoners, many of them political. This has been done because typhus is rampant in the camp and it is vital that no prisoners be released until the infection is checked. The advancing British agreed to refrain from bombing or shelling the area of the camp, and the Germans agreed to leave behind an armed guard which would be allowed to return to their own lines a week after the British arrival. The story of the negotiations is curious. Two German officers presented themselves before the British outposts and explained that there were 9,000 sick in the camp and that all sanitation had failed. They proposed that the British should occupy the camp at once, as the responsibility was international in the interests of health. In return for the delay caused by the truce the Germans offered to surrender intact the bridges over the river Aller. After brief consideration the British senior officer rejected the German proposals, saying it was necessary that the British should occupy an area of 10 kilometers round the camp in order to be sure of keeping their troops and lines of communication away from the disease. The British eventually took over the camp.

Medical Delegations to Britain from Liberated Europe

It was stated in a previous letter (THE JOURNAL, March p. 610) that the doctors and scientists of liberated Eur are eagerly looking to Britain for a cultural lead to repl the hegemony hitherto exercised by Berlin. Signs of t movement are already evident. A French medical delegati is now visiting this country as guests of the British Coun and the Royal College of Physicians. Representing the Ac démie de médecine is Prof. A. Baudouin, dean of the Facul de médecine, Paris, Prof. A. Lemierre and Dr. P. F. Arman Delille; the Conseil supérieur de médecine, Dr. Ravina, D A. Laporte and Dr. H. Descomps; the provinces, Prof. Soula of Toulouse, Professor Gernez-Rieux of Lille, Prof. Roche of Marseilles and Dr. M. Nédelec of Angers. Durin the blight of the German occupation of France not only di all progress in medicine and science cease but the countr was cut off from the outside world, so that advances mad remained unknown. Even foreign medical journals could not be obtained.

Arrangements have also been made for the visit to Britain of four groups of Belgian professors in the next three months. The first group will be here from April 16 to 30 and will include N. Goormaghtigh of Ghent and Prof. P. Govaerts of Brussels.

SWITZERLAND

(From Our Regular Correspondent)

GENEVA, April 15, 1945.

Swiss Tropical Institute

It is now one year since the Swiss Tropical Institute was founded in Basle. It has witnessed a considerable development under the direction of its president, Professor R. Geigy. There are now more than a hundred students following different courses on tropical subjects. A special section has been created for the documentation and the bibliography of all tropical matters. This section serves scientists or businessmen by furnishing required information about publications concerning the tropics. The library is enlarging every day and comprises at present four hundred books, fifty periodicals and more than a thousand pamphlets, articles and other items. The institute also publishes a review, the *Acta tropica*, of which four issues appeared in 1944. The institute has created, at the Basle Auxiliary Hospital, a special section for tropical diseases. The immediate purpose of this clinic, which is under the direct control of the institute, was to receive Italian and Yugoslavian military internees suffering from malaria. During the last six months of 1944, 163 patients were treated. The observations made enabled the doctors and students to start research on hematology, serology and medical entomology. The director of the clinic is Dr. A. Perret-Gentil, medical adviser of the institute, assisted by Dr. M. Lauterburg-Bonjour.

The Fight Against Cancer

It is estimated that 1 person out of 7 dies of cancer in Switzerland. Therefore the Swiss Association for the Fight Against Cancer has started a vast propaganda action throughout Switzerland to make people conscious of the danger of the disease. To give to this action the greatest efficiency, the association has had a documentary film made about cancer. The film was done with the help of Swiss specialists and the laboratories of medical schools. It enables the public to witness operations at which only doctors are usually present. The actor

Biberti, who impersonates a professor of pathology, explains to his students (and therefore for the public in the cinema) the theories concerning cancer and the different therapeutic methods now in use. The film lasts one hour, and the audience can become acquainted with the appearance of different kinds of cancer and the stages of their evolution. It shows the principal methods of treatment: removal of the cancer focus, destruction of the cancer cells with roentgen rays and radium therapy. As it is essential for a good prognosis to be able to diagnose very early the formation of a focus, the film emphasizes the value of a complete medical examination at least once a year.

Center for Types of Bacteria in Lausanne

A special laboratory has just been established at the Institute for Hygiene and Bacteriology of the Lausanne Medical School where specimens of all organisms pathogenic for man, animals and plants will be kept. This laboratory will function with the help of well known Swiss and foreign workers, and the specimens will be sent to any doctor doing research who asks for them. A detailed catalogue will help him to choose the exact variety of germs he wishes to have. The Swiss Academy of Medical Sciences has given its approval to this new center, and Dr. P. Hauduroy, professor of bacteriology, has been appointed as its director.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, April 18, 1945.

Observations on the BCG Immunization Campaign

The campaign for the immunization of Rio de Janeiro infants against tuberculosis by the BCG vaccine under the direction of Dr. Arlindo de Assis has been reported in several previous letters. Dr. Assis has just published a general report of his work begun in 1927, which includes, up to 1944, a total of 161,152 immunized children. At the same time the report includes the vaccination of more than 3,000 anallergic persons of other age groups. The immunizing strain used was obtained in 1927 from Dr. E. Moreau of Montevideo, Uruguay, the material having been originally furnished by Dr. Calmette from the Pasteur Institute in Paris. As a rule the immunizations were performed through the ingestion of the material, but in some cases subcutaneous and intradermal inoculations were used as well. In 1934 Dr. Assis began to immunize anallergic children of preschool and school ages, for which he used the total dose of 10 centigrams. All this immunization work has been accompanied by extensive laboratory researches, which in part have been reported in previous letters.

The Moreau strain of BCG, studied in animals since 1925 and in human beings since 1927, has maintained, up to now, the original attenuated virulence and the capacity of producing tuberculin and tuberculinic allergy. When killed by heat and administered intradermally to nontuberculous individuals in the dosage of one tenth of a milligram, the strain may cause minimal nodules, sometimes followed by suppuration or transient local caseation, associated or not with late tuberculinic allergy (after the third week). Sometimes it may stimulate only the appearance of this late tuberculinic allergy, without the production of local nodules. In about 45 per cent of the cases it may cause no change at all. The same dosage of killed BCG, in tuberculous patients during the preallergic stage, or in tuberculinized individuals who have already lost their allergy, or in BCG immunized individuals also apparently anallergic, the intradermal inoculation shows a quite different picture, causing the early appearance of intense nodular reaction and the state of cutaneous tuberculinic allergy during the first week. This ability to produce what Dr. Assis calls "infratuberculinic allergy" (THE JOURNAL, Nov. 28, 1942, p. 1053) is comparatively stronger than the same effect caused by the common human virulent tubercle bacillus.

A High Standard School of Nursing

A new high standard school of nursing has been founded in Nicteroy, state of Rio de Janeiro. This is the third nursing school of this type in Brazil and the second one founded with the cooperation of the Special Service of Public Health. As reported in a previous letter (THE JOURNAL, Aug. 14, 1943, p. 1140), a school of nursing of high standard was founded in June 1943 in connection with the University of São Paulo. For the establishment of this school the Special Service made large contributions. It is interesting to point out that the first school of nursing of high standard—the one now belonging to the University of Rio de Janeiro—was founded in 1923 with the cooperation of a mission of American nurses supported by the International Health Board of the Rockefeller Foundation.

Dr. Leo Eloesser

Dr. Leo Eloesser, professor of Surgery at the Stanford University, spent a few days in Rio de Janeiro, commissioned by the Rockefeller Foundation to study some aspects of surgery and its teaching in Brazil and in other South American countries. Dr. Eloesser visited the department of surgery of the Hospital Moncorvo Filho, under the direction of Dr. Alfredo Monteiro, where he delivered a lecture on the modern evolution of pulmonary surgery. He was also received at the Brazilian College of Surgeons and at the Brazilian Tuberculosis Association, where he spoke respectively on war surgery of the thorax and on the treatment of tuberculous lung cavities.

American Penicillin in Brazil

The use of penicillin is rapidly developing in Brazil, although the drug is mainly distributed as a solution, the form in which it is prepared and furnished by the Institute Oswaldo Cruz of Rio de Janeiro. However, since June of last year American dried sodium penicillin has been available. To insure the regular distribution of the drug throughout the whole country, a control of the use was established by the National Health Department, but this measure is being suspended gradually, as the importation of American penicillin has increased rapidly.

Personal

Dr. Hercilio Marroco has been appointed president of the Sociedade Medica São Lucas for 1945-1946.

Dr. Antonio Murtinho Nobre, well known Brazilian homeopathist, died suddenly in Rio de Janeiro on April 1, aged 66.

Dr. Eurico Branco Ribeiro, director of Sanatorio São Lucas of São Paulo, has been elected corresponding member of the Academia de Letras do Paraná.

Marriages

BENJAMIN FRANKLIN MONTAGUE Jr., Charleston, W. Va., to Miss Mary Louise Aylor of Chatham, Va., March 3.

WILLIAMS MCIVER BRYAN Jr., Cleveland, to Miss Anne (Nancy) Gantt Snowden of Columbia, S. C., April 10.

THEOPHILUS HENRY BOYSEN III, Egg Harbor, N. J., to Miss Jean Danaher of Philadelphia, February 10.

HARRY EUGENE EZELL Jr., Corsicana, Texas, to Miss Miriam Jordan Akin of Franklin, Tenn., March 9.

ROBERT DUDLEY PILLSBURY, Omaha, to Miss Margaret Jane Schwab of Washington, D. C., January 27.

FRANCIS A. MARZONI, Durham, N. C., to Miss Florence Dick of Paris, Ky., in Durham, April 6.

LEO M. BASHINSKY, Durham, N. C., to Miss Betty Louise Riddle in Burlington, April 1.

HAROLD D. HILL to Miss Marjorie Ellen McCain, both of Richmond, Ind., February 11.

JOSEPH D. BELLEVILLE to Miss Marilyn Scott, both of St. Louis, March 1.

Deaths

Martin Henry Dawson, New York; McGill University Faculty of Medicine, Montreal, Que., Canada, 1923; instructor in pathology and bacteriology at the University of Louisville School of Medicine, Louisville, Ky., 1924-1925; in 1926 joined the Rockefeller Institute, New York, as research fellow, becoming an assistant in 1928; later served as associate professor of clinical medicine at the Columbia University College of Physicians and Surgeons; associate physician at the Presbyterian Hospital; won the military cross for service during World War I as a captain in the Trench Mortar Battery of the Canadian army; specialist certified by the American Board of Internal Medicine; member of the Association of American Physicians, American Society for Clinical Investigation, American Rheumatism Association, American Association of Pathologists and Bacteriologists, American Society for Experimental Pathology and the Society of American Bacteriologists; executive secretary of the International Congress on Microbiology and editor of its transactions; during World War II director of the Commission on Streptococcal Infections under the War Department and consultant on infectious diseases to the Secretary of War; directed a comparative research program which included the treatment of bacterial endocarditis with penicillin and the use of gold salts in the treatment of rheumatoid arthritis; said to be first in the United States to prepare and use penicillin for treatment of human beings; research included infectious diseases, the transmutation of strains of pneumococci and biologic variants of the streptococcus and other microorganisms and the nature and treatment of arthritis; died in the Harkness Pavilion, Columbia-Presbyterian Medical Center, April 27, aged 48.

Milton Weston Hall ⊕ Lieutenant Colonel, U. S. Army, retired, Palma Sola, Fla.; S.B., Massachusetts Institute of Technology, in 1900; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1903; Army Medical School, advanced course, 1921; served during World War I; entered the medical corps of the U. S. Army as a major in 1920; promoted to lieutenant colonel in August 1937; retired Jan. 31, 1942; was placed on active duty Feb. 1, 1942, serving as associate professor of military science at the State University of Iowa College of Medicine, Iowa City; returned to the inactive retired list about April 15, 1944; member of the Medical Association of the Isthmian Canal Zone, American Society of Tropical Medicine and the Association of Military Surgeons of the United States; his service included three years' work on dengue fever with the research board on tropical diseases in the Philippines and with General Hospital laboratories in this country and in Panama; died March 26, aged 67, of myocardial insufficiency, influenza and arteriosclerosis.

Marion Whitmell Ransone ⊕ Captain, U. S. Army, retired, Washington, D. C.; Medical College of Virginia, Richmond, 1926; interned at the Walter Reed General Hospital; Army Medical School and Medical Field Service School in 1928; served during World War I; entered the medical corps of the U. S. Army as a first lieutenant in August 1927; promoted to captain in August 1929; retired on April 30, 1937 for disability in line of duty; assistant professor of pathology at the Georgetown University School of Medicine; on the staffs of the Georgetown University and Gallinger Municipal hospitals; died in the Alexandria Hospital, Alexandria, Va., March 17, aged 47, of coronary thrombosis.

Robert DuVal Jones, New Bern, N. C.; University of Maryland School of Medicine, Baltimore, 1896; member of the American Medical Association and the Southern Surgical Association; served as president of the North Carolina Hospital Association and as district president of the Medical Society of the State of North Carolina; fellow of the American College of Surgeons; a lieutenant commander in the U. S. Navy serving overseas during World War I; at one time county physician; formerly associated with the U. S. Public Health Service; manager of St. Luke's Hospital, in which he was part owner until he retired; died March 2, aged 71, of heart disease.

John McEwen Foster, Denver; University of Tennessee Medical Department, Nashville, 1891; member of the American Medical Association and the American Laryngological, Rhinological and Otological Society; honorary member of the Colorado State Medical Society; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; professor of otolaryngology emeritus at the University of Colorado School of Medicine; member of the consulting staff, St. Luke's Hospital; consulting ophthalmologi at the Children's Hospital; died March 24, aged 84, of cardi renal failure and anemia.

Henry Clarence Lochte, New Orleans; Tulane Universi of Louisiana School of Medicine, New Orleans, 1914; serv as instructor in clinical medicine at his alma mater; an offic in the medical corps of the U. S. Army during World War I for many years associated with the bureau of war risk insuran of the Veterans Administration; formerly assistant bacteriologi for the city board of health; chief of the outpatient division the Veterans Administration Facility in Bay Pines, Fla., fro 1933 to 1938, when he retired; died March 25, aged 53, hypertensive cardiovascular disease.

Andrew John Aird, Carterville, Ill.; Barnes Medical Co lege, St. Louis, 1898; served during World War I; died i the Veterans Administration Facility, Marion, Ind., March 1 aged 77, of hypertensive heart disease.

Einer Bjarne Andersen ⊕ Iron Mountain, Mich.; Univer sity of Michigan Medical School, Ann Arbor, 1919; fellow o the American College of Surgeons; secretary-treasurer of th Dickinson-Iron Counties Medical Society; staff member, Iro Mountain General Hospital; died April 22, aged 52, of hear disease.

Robert Bailin, Brooklyn; New York Homeopathic Medica College and Flower Hospital, New York, 1917; member o the American Medical Association; died February 12, age 52.

Will Lake Beach ⊕ Painesville, Ohio; Ohio State Univer sity College of Medicine, Columbus, 1920; died March 13 aged 54.

Aubry C. Belcher, Richmond, Va.; Medical College of Virginia, Richmond, 1916; member of the American Medical Association; died February 18, aged 55.

Stephen Albert Bergin, Worcester, Mass.; Harvard Medical School, Boston, 1900; member of the American Medical Association; obstetrician at St. Vincent Hospital, where he died February 21, aged 72, of arteriosclerotic heart disease, chronic nephritis and diabetes mellitus.

Abram Louis Blanding, Fountain Inn, S. C.; University of Maryland School of Medicine, Baltimore, 1881; died February 25, aged 86.

George Dorsey Boone, Erin, Tenn.; University of Nashville Medical Department, 1899; served as mayor of the town of Erin; died in the Nobles Memorial Hospital, Paris, March 6, aged 73, of cerebral hemorrhage.

Albert Ubald Bourcier, Springfield, Mass.; University of Montreal Faculty of Medicine, Montreal, Que., Canada, 1927; member of the New England Society of Psychiatry; captain in the medical corps, Army of the United States, from Aug. 21, 1942 until Nov. 28, 1942, when he was relieved from duty; served on the staffs of the Northampton State Hospital and the Cooley Dickinson Hospital, Northampton, and the Mercy Hospital, where he died March 5, aged 47, of skull fracture and subdural hemorrhage caused by a fall.

Augustus A. Bradley, Cookeville, Tenn.; University of Tennessee Medical Department, Nashville, 1901; member of the American Medical Association; died February 15, aged 78.

Devillo N. Bulson, Rockville Centre, N. Y.; Eclectic Medical College of the City of New York, 1886; member of the board of education; one of the members of the board of trustees who founded the Rockville Centre Public Library; founder and for many years president of the Nassau County National Bank; died March 22, aged 89, of heart disease and pneumonia.

William Taylor Center ⊕ Hazel Green, Ky.; Hospital College of Medicine, Louisville, 1907; died February 25, aged 63.

Peter David Cholodny, Elizabeth, N. J.; Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1921; plant physician for the U. S. Metals Refining Company at Carteret; interned at the Alexian Brothers Hospital, where he died March 4, aged 51, of coronary thrombosis.

John William Christensen, Dayton, Ohio; Milwaukee Medical College, 1902; served during World War I; served on the staff of the Veterans Administration Facility, where he died March 18, aged 70, of coronary occlusion due to hypertensive heart disease.

John Henry Francis Connor, Wrentham, Mass.; College of Physicians and Surgeons, Boston, 1907; assistant physician at the Wrentham State School; for many years an examiner for the Massachusetts Boxing Commission; died March 8, aged 63.

Francis M. Corry, Menasha, Wis.; Milwaukee Medical College, 1900; died in St. Elizabeth Hospital, Appleton, April 7, aged 69, of coronary thrombosis.

Frank Adams Daugherty, Independence, Ky.; University of Louisville School of Medicine, 1925; member of the American Medical Association; interned at the Good Samaritan Hospital in Cincinnati; a member of the Students Advanced Training Corps during World War I; on the courtesy staff of the William Booth Memorial Hospital in Covington, where he died March 16, aged 47, of malignant hypertension.

John Franklin Davis ⊕ Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910; served in the medical corps of the U. S. Army during World War I; for many years physician for the Chicago Bears football and the Cubs baseball teams; surgeon for the Rapid Transit Lines; member of the attending staff of the Illinois Masonic Hospital, where he died April 6, aged 69, of bundle branch block and coronary thrombosis.

William Eugene Dickinson, Canistota, S. D.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; served during World War I; veteran of the Spanish-American War; died January 28, aged 67.

John Wesley Dill, Los Angeles; University of Michigan Homeopathic Medical School, Ann Arbor 1879; Civil War veteran; died April 2, aged 102, of pneumonia.

Abraham Wilson Dods, Fredonia, N. Y.; the Hahnemann Medical College and Hospital, Chicago, 1878; member of the American Medical Association; examining physician for the local draft board during World War I; an honorary member of the Rotary Club, the Fredonia chamber of commerce, of which he served once as president, and the Chautauqua County Medical Association; served as surgeon at the Brooks Memorial Hospital, Dunkirk, and with the New York Central Railroad Company; died April 6, aged 91, of senility.

William Evans ⊕ West Chester, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1885; served as physician at the Pennsylvania Industrial Home for Blind Women and the Home for Aged and Infirm Colored Persons; member of the board of directors of the Elwyn Training School in Elwyn, and the Y. M. C. A. in West Chester; member of the College of Physicians of Philadelphia; died in the Chester County Hospital March 18, aged 83, following a prostatectomy.

Carlos Sager Fenton, North Bloomfield, Ohio; University of Wooster Medical Department, Cleveland, 1891; died March 15, aged 79.

George Horace Gilbert, Austin, Texas; University of Texas School of Medicine, Galveston, 1903; member of the American Medical Association; served during World War I; died in St. David's Hospital February 17, aged 65, of encephalitis.

Heber M. Goodsmith, Evanston, Ill.; College of Physicians and Surgeons of Chicago, 1887; formerly member of the medical staff of the Metropolitan Life Insurance Company and medical director of the Illinois Bell Telephone Company in Chicago; died April 9, aged 79, of chronic myocarditis.

George DeWayne Hallett, New York; New York Homeopathic Medical College and Hospital, New York, 1889; specialist certified by the American Board of Ophthalmology; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the staffs of the Jamaica Hospital, Jamaica, and the Flower and Fifth Avenue Hospitals; died March 14, aged 78, of heart disease.

William C. Harris, Lawrenceburg, Tenn. (licensed in Tennessee in 1889); died in Nashville March 6, aged 86, of cerebral hemorrhage.

Robert Galloway Henderson ⊕ Memphis, Tenn.; Memphis Hospital Medical College, 1900; died February 9, aged 69.

Clare Fredric Hoover ⊕ Topeka, Kan.; Kansas Medical College, Topeka, 1899; on the staffs of the Stormont Hospital and Christ's Hospital, where he died February 9, aged 70, of auricular fibrillation and gangrene of the leg from embolism.

Walter Dennis Hough, Los Angeles; New York Homeopathic Medical College, New York, 1881; Long Island College Hospital, Brooklyn, 1883; died January 13, aged 86.

William C. Hunt, Rochester, Ky.; University of Louisville Medical Department, 1889; died in Browder March 26, aged 86, of angina pectoris.

Andrew Jackson Hunter, Eureka, Mont.; the Hahnemann Medical College and Hospital, Chicago, 1883; died January 26, aged 93, of arteriosclerosis.

Martin Bushnell Jelliffe ⊕ Springfield, Ill.; University of Illinois College of Medicine, Chicago, 1917; served during World War I; interned at the Cook County Hospital in Chicago; on the staffs of the Memorial Hospital and St. John's Hospital, where he died March 5, aged 55, of diabetes mellitus and coronary occlusion.

Brinley John, Morgantown, W. Va.; Jefferson Medical College of Philadelphia, 1924; member of the American Medical Association; served as president of the Monongalia County Medical Society in 1935; interned at the South Side Hospital in Pittsburgh; died April 21, aged 45, of coronary thrombosis.

Joseph Frasia Jones, Richmond, Va.; Medical College of Virginia, Richmond, 1906; member of the American Medical Association; at one time demonstrator of anatomy at his alma mater; formerly assistant surgeon for the Seaboard Air Line Railway; on the staff of the Johnston-Willis Hospital; died March 11, aged 66, of coronary occlusion.

Edward F. Katzman, Louisville, Ky.; Louisville Medical College, 1902; member of the American Medical Association; died in St. Joseph Infirmary March 15, aged 64, of hypertensive heart disease.

Joseph Lemuel Kershner, Effingham, Ill.; Marion-Sims College of Medicine, St. Louis, 1892; died in St. Anthony's Hospital March 13, aged 86, of chronic cardiovascular sclerosis.

Emanuel Klaus ⊕ Cleveland; Western Reserve University Medical Department, Cleveland, 1902; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served in the medical corps of the U. S. Army during World War I; executive secretary of the International Anesthesia Research Society and member of other associated groups; member of the staff of the Lutheran Hospital, where he died March 21, aged 69, of arteriosclerotic heart disease and pulmonary infarction.

Oscar Kenneth Lang, New York; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1906; died March 10, aged 63.

Henry Austin Macheca, New Orleans; Tulane University of Louisiana School of Medicine, New Orleans, 1921; served on the teaching staffs at his alma mater and the Louisiana State University Medical Center; interned at the Touro Infirmary, where he served on the staff; formerly on the staff of the Charity Hospital; died March 19, aged 48, of heart disease.

Arthur Morgan MacWhinnie, Seattle; Baltimore Medical College, 1897; member of the Pacific Coast Oto-Ophthalmological Society; died February 28, aged 70, of arteriosclerosis and cardiorenal disease.

Anna Manning, Jersey City, N. J.; Woman's Medical College of the New York Infirmary for Women and Children, New York, 1893; died February 7, aged 85.

Edward Earl Marsh, Wilkes-Barre, Pa.; Medico-Chirurgical College of Philadelphia, 1916; member of the American Medical Association; served during World War I; died January 25, aged 51.

Lewis Martin, Newton, Ill.; Eclectic Medical Institute, Cincinnati, 1894; died February 12, aged 85.

John George Maurer ⊕ Saginaw, Mich.; Saginaw Valley Medical College, 1902; died March 9, aged 67, of coronary occlusion.

Charles F. Mayer, Burr, Neb.; John A. Creighton Medical College, Omaha, 1904; member of the American Medical Association; on the courtesy staff of the Bryan Memorial Hospital, Lincoln, where he died January 23, aged 65.

William Hayes McCarty, Marion, Va.; Medical College of Virginia, Richmond, 1924; member of the American Medical Association and the American Psychiatric Association; served during World War I; interned at the George Ben Johnston Memorial Hospital, Abingdon; for many years a member of the staff of the Southwestern State Hospital; died January 26, aged 47.

Robert Lane McCrady ⊕ Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1912; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; professor of gynecology and obstetrics and member of the library committee and advisory committee to the dean at his alma mater; member of the board of commissioners and surgical staff of the Roper Hospital; found in the creek near his summer cottage on James Island, April 3, aged 55.

Thomas Francis McDermott, New York; Medical College of Virginia, Richmond, 1924; on the staff of St. Vincent's Hospital; died February 11, aged 52.

Herbert Edmund McLean ⊕ Jersey City, N. J.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1923; on the staff of the Christ Hospital; died January 9, aged 47.

Caleb Gleni McNaul, Altoona, Pa.; Jefferson Medical College of Philadelphia, 1890; served as medical inspector in the Juniata schools for twenty years; died in the Altoona Hospital January 21, aged 79.

Archie Levy Oberdorfer, New York; University of Virginia Department of Medicine, Charlottesville, 1901; member of the American Medical Association; served on the staffs of the Mount Sinai and Harlem Eye and Ear hospitals; died March 12, aged 67.

James C. Paxson, Charleston, Ill.; Medical College of Ohio, Cincinnati, 1883; died in the M. A. Montgomery Memorial Sanitarium March 9, aged 89, of toxemia and carcinoma of the penis.

Thorvald Petersen ⊕ Minneapolis; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1911; fellow of the American College of Surgeons; member of the surgical staff of the Fairview Hospital; died January 22, aged 62, of cerebral thrombosis.

Fred Saul Richmond, Bluefield, W. Va.; University of Louisville Medical Department, Louisville, Ky., 1911; member of the American Medical Association; died in the Bluefield Sanitarium April 9, aged 61, of cerebral hemorrhage.

Hugh Fay Ringo, Milwaukee; University of Louisville Medical Department, Louisville, Ky., 1907; member of the American College of Chest Physicians; died February aged 60.

Douglas H. Roberts, Lincoln, Neb.; Lincoln Medical College of Cotner University, 1896; for many years president of the board of education and formerly mayor of Bethany; died February 4, aged 84.

Samuel Jacob Schwaup, Osborne, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1906; member of the American Medical Association; died February 4, aged 65.

Claude Martin Walker ⊕ Kellerton, Iowa; St. Louis College of Physicians and Surgeons, 1898; served as a member of the board of health; died in March, aged 71, of carcinoma

John Alexander Williams, Walton, Fla. (licensed in Indiana in 1899); for many years a practitioner in Fort Wayne, Ind.; died February 16, aged 83, of chronic valvular heart disease and generalized anasarca.

LIEUT. WALTER GEORGE EPPLY
(MC), U.S.N.R., 1916-1944

LIEUT. AKIN MATHIEU
(MC), U.S.N.R., 1917-1944

CAPT. ORVILLE DONALD THATCHER
M. C., A. U. S., 1913-1944

Daniel Warren Poor, Narrowsburg, N. Y.; College of Physicians and Surgeons, New York, 1894; associated with the department of health of New York City for more than twenty-five years, retiring in 1929 as assistant director of the bureau of laboratories; died March 29, aged 75.

Julius Wollitzer ⊕ Johnstown, Pa; University of Kolozsvar, Hungary, 1906; interned at St. Luke's Hospital in Bethlehem; a captain in the Hungarian army medical corps during World I; died in the Conemaugh Valley Memorial Hospital February 11, aged 64, of carcinoma of the sigmoid

KILLED IN ACTION

Walter George Epply, Manchester, N. H.; McGill University Faculty of Medicine, Montreal, Que., Canada, 1941; interned at the Vancouver General Hospital, Vancouver, B. C., Canada; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on Aug. 7, 1942; left the United States about June 20, 1943; spent some time in New Caledonia; on Aug. 14, 1943 assigned to the U. S. S. *President Adams;* promoted to lieutenant on Oct. 1, 1943; awarded the Silver Star Medal posthumously; the citation accompanying the award read "for conspicuous gallantry and intrepidity as officer in charge of the medical section of a beach party during the assault on enemy Japanese-held Asan Point, Guam, Marianas Islands, on July 21, 1944"; he was killed in the action for which he received the medal, aged 27.

Akin Mathieu, Portland, Ore.; University of Oregon Medical School, Portland, 1942; served an internship at the Robert Packer Hospital, Sayre, Pa.; commissioned a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on June 12, 1942; promoted to lieutenant on Nov. 1, 1944; died in the Asiatic area Oct. 25, 1944, aged 27, of extreme multiple injuries

Orville Donald Thatcher, Fort Dodge, Iowa; State University of Iowa College of Medicine, Iowa City, 1937; interned and served a residency at the University Hospitals, Iowa City; member of the American Medical Association; commissioned a first lieutenant in the medical corps, Army of the United States, on June 29, 1942; began active duty on July 11, 1942; a flight surgeon assigned to the 386th Bombardment Group (M) of the Ninth Air Force based in England; promoted to captain, awarded the Purple Heart posthumously; killed in action in France June 22, 1944, aged 31.

IDENTIFICATION CARD FOR BLOOD DONORS

To the Editor:—As director of the Blood Bank of Queens County it seems to me quite necessary that every person should know his blood type and Rh factor and carry a card with the information on his person at all times.

In the work we started here in 1942 we have typed more than 5,000 people in and around Queens County. Several large business concerns have a list of these types in their files so that in an emergency one or more compatible donors may be sent to the hospital when the patient is admitted.

We have determined the Rh factor on the last 2,000 and have a voluntary list of 185 Rh negative donors of all types available on call for emergencies.

All persons typed have in addition to their own type and Rh factor the names of six persons of their acquaintance of the same type and Rh factor on their identification card. All of this saves valuable time at the critical moment and does away with the unnecessary confusion and loss of time trying to locate a donor of the proper type.

BLOOD BANK of QUEENS COUNTY, INC.
152nd Street and 89th Avenue
Jamaica, N. Y.
Phone, JAmaica 6-4226

DONORS HONOR ROLL

Name _____

Address _____

Type _____ Rh. _____

Identification card, showing blood type and Rh factor. On the back of the card, under the heading "Persons of My Type and Rh Factor," are blank lines for six names.

This is a nonprofit organization and all blood and plasma is given free on the replacement plan of two donors for each unit when we can get it. No patient is denied blood or plasma regardless of ability to send in replacements.

We are doing a typing program for the New York City Police Department so that it may have in addition to its regular typing list a list of Rh negatives of all types.

Such a plan as this could be adopted nationally by the Red Cross as a postwar project.

We are soon to start an enlarged program of this kind in Brooklyn under the auspices of the Kings County Medical Society.

EDWARD J. MADDEN, Jamaica, N. Y.

PRIORITY IN REFRIGERATION

To the Editor:—The paper of Blakemore and his collaborators in THE JOURNAL, March 24, continues the misstatement of their former publication (*Ann. Surg.* **117**:481 [April] 1943) crediting the introduction and demonstration of the refrigeration principle to Brooks and Duncan. The following facts should scarcely be overlooked: (*a*) The prior work of F. M. Allen was acknowledged in the very paper of Brooks and Duncan which Blakemore et al. cite, and Allen's experiments were much greater in number and scope and are well known as the origin of current interest in this method. (*b*) The Brooks and Duncan experiments have subsequently been interpreted (Brooks, discussion, *Ann. Surg.* **115**:626 [April] 1942. Large and Heinbecker, *ibid* **120**:707 [Nov.] 1944) as adverse to the preservation of tissue demonstrated by Allen and with emphasis on alleged destructive effects of cold, thus making the position of Blakemore et al. all the more unreasonable. (*c*) Allen has recently (*Arch. Phys. Med.* **26**:92 [Feb.] 1945) pointed out the errors in the methods and interpretation of the Brooks-Duncan and Large-Heinbecker experiments and interpretations. This treatment of the recorded literature is called to attention because of my impression that it is not an isolated incident.

LYMAN WEEKS CROSSMAN, M.D., New York.

CENTENARY CELEBRATION OF LAWSON TAIT

To the Editor:—Lawson Tait was born on May 1, 1845. Arrangements are being made in Birmingham, England, where his life's work was done, to celebrate his centenary in 1945.

We should be grateful for any matter of interest concerning Lawson Tait from American medical men, many of whom visited him at the Crescent, Birmingham, in the latter years of last century and by whom credit for his pioneer work in abdominal surgery was generously given.

It is hoped to arrange a meeting of the profession in Birmingham and perhaps also to arrange a small exhibition representative of his life and writings.

FAUSET WELSH.
F. SELBY TAIT.
Birmingham Medical Institute,

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Service Plans Not Insurance nor the Corporate Practice of Medicine.—California Physicians' Service was incorporated as a nonprofit membership corporation in 1939 under the applicable laws of California. It is composed of beneficiary members, professional members and administrative members. A beneficiary member is entitled on the payment of stated monthly dues and when the necessity for medical or surgical service for him arises to select any professional member to render those services to him at the cost of the corporation. Professional members are such physicians as agree to abide by the rules of the corporation, and any physician licensed to practice medicine in California is eligible to become a professional member. A professional member agrees that in return for the services he renders a beneficiary member he will accept compensation "upon a pro rata basis out of the monthly funds collected from the beneficiary members." The administrative members comprise physicians and others in whom is vested the administrative control of the corporation. Shortly after its incorporation the corporation undertook to operate a medical service plan throughout the state. In 1941 a law was enacted in California (Civil Code, Sec. 593a) which, in effect, authorized the organization and operation of a corporation such as the California Physicians' Service if, among other things, one fourth of the licensed physicians in the state became professional

members and if the corporation was licensed by the Board of Medical Examiners.[1] Following the enactment of this law the corporation obtained a license from the board of medical examiners. Nevertheless the insurance commissioner believed it necessary for the corporation to qualify under the insurance laws of the state and apparently threatened legal action. Thereupon the corporation instituted against the insurance commissioner an action for a declaratory judgment that its operations did not "constitute insurance under the supervision of the commissioner nor the corporate practice of medicine." There was a judgment for the corporation, and the commissioner appealed to the district court of appeal, first district, division 2, California.

The insurance commissioner contended, first, that the corporation was illegally engaged in the practice of medicine, citing *Painless Parker* v. *Board of Dental Examiners,* 216 Cal. 285, 14 P. (2d) 67; *People ex rel. State Board of Medical Examiners* v. *Pacific Health Corporation,* 12 Cal. (2d) 156, 82 P. (2d) 429, 119 A. L. R. 1284; *Benjamin Franklin Life Assur. Co.* v. *Mitchell,* 14 Cal. App. (2d) 654, 58 P. (2d) 984, which cases hold that a corporation may not lawfully engage in the practice of law, medicine or dentistry. The corporation did not dispute the rule enunciated in those cases, but it contended that its practices were expressly sanctioned by the 1941 law previously referred to. It also relied on certain statements in the *Pacific Health Corporation* case, supra. There it was said that the rule prohibiting the corporate practice of medicine did not apply to the furnishing of medical services to members by fraternal, religious, hospital, labor and similar benevolent organizations. That case further said that the distinguishing feature was whether an association or corporation was organized for profit. Further, in the words of the court in that case the activities of these nonprofit organizations were "not comparable to those of private corporations operated for profit and, since the principal evils attendant upon corporate practice of medicine spring from the conflict between the professional standards and obligations of the doctors and the profit motive of the corporation employer, it may well be concluded that the objections of policy do not apply to nonprofit institutions. This view almost seems implicit in the decisions of the courts, and it certainly has been the assumption of the public authorities, which have, as far as we are advised, never molested these organizations." In answer, the commissioner argued that the law relied on by the corporation cannot have the effect of validating its activities since it merely authorized the incorporation for the purposes stated whereas the California Physicians' Service was organized two years prior to the enactment of the law. If this case, answered the court, involved prosecution for the acts committed before the statute was passed there would be some merit in the argument. But it is concerned only with a declaration of the right of respondent to continue under the section free from the supervision of the insurance commissioner. Since it is conceded that the legislature intended the statute to apply to California Physicians' Service, it is a fair inference that the legislature had some knowledge of the practice and mode of operation of the corporation and hence the legislative intent was to permit the respondent to continue in those activities under the terms of the law it enacted.

The insurance commissioner contended, finally, that California Physicians' Service was engaged in the insurance business and hence subject to his supervision and control. In answer, the corporation argued that, first, its method of operation is not that of insurance and, secondly, if it is insurance the corporation is not subject to the supervision of the commissioner. Insurance, said the court, is defined in section 22 of the Insurance Code as "a contract whereby one undertakes to indemnify another against loss, damage or liability arising from a contingent or unknown event." St. 1935, p. 498. It is defined in 29 Am. Jur. p. 47 as "an agreement by which one person for a consideration promises to pay money or its equivalent, or to perform some act of value, to another on the destruction, death, loss or injury of someone or something by specified perils." The commissioner cited no authority directly in point. He argued that the obligation to the beneficiary members assumed by California Physicians' Service looks like insurance and should be so interpreted. On the other hand, the corporation argued that it is similar to a producer-consumer cooperative organization, that it does not indemnify or compensate for the cost of an illness or injury, that it does not assume any risk, that its professional members do not assume any risk and that the beneficiary members do not receive any indemnity or compensation. The corporation emphasized that its obligation was that of an agent to collect and administer funds collected from beneficiary members and to pay its professional members on the unit basis out of these funds only, but that the beneficiary members receive the professional services notwithstanding the condition of the treasury. The corporation denied an implication in the commissioner's brief that the beneficiary members must look to the pooled fund for indemnity against medical bills and the corporation emphasized that the beneficiary members merely pay for such services on a periodic basis rather than in a lump sum. As the operations of California Physicians' Service, said the court, are comparatively new there is little authority on the direct question as to whether or not these operations are to be classed as insurance. The decided cases favor the corporation's position. In *Butterworth* v. *Boyd,* 12 Cal. (2d) 140, 82 P. (2d) 434, 126 A. L. R. 838, the facts were these: The San Francisco charter provided, in part, compulsory health service to all municipal employees to be paid for by monthly pay roll deductions on all salaries to maintain a fund to cover medical, surgical and hospital care. Physicians eligible to render service were paid on the unit system similar to that used by the corporation. In an action brought to test the validity of the charter the state insurance commissioner appeared specially to raise the question as to whether the activities in question were a form of insurance and as such subject to the state insurance code. The court there said that the Insurance Code dealt only with the private business of insurance. In *Commissioner of Bank and Insurance* v. *Community Health Service,* 129 N. J. L. 427, 30 A. (2d) 44, the sole question involved was whether or not the corporation was engaged in the insurance business. It was incorporated to provide medical services to its subscribers. It made contracts with licensed physicians to render professional services for a stipulated compensation. The subscribers were entitled to the services whether or not they needed them. The corporation did not, in the words of the California court, undertake to pay such debt as the subscribers might incur and did not indemnify them against any loss. The New Jersey court said:

> Neither as between the corporation and the physician nor as between the physician and the subscriber is the compensation or any other element of the arrangement between them affected by any contingency, hazard or risk.

In holding that the business conducted by the corporation was not one of insurance, the New Jersey court cited with approval *State ex rel. Fishback* v. *Universal Service Agency,* 87 Wash. 413, 151 P. 768, Ann. Cas. 1916C, 1017; *Sisters of Third Order*

1. Specifically this law, so far as is here material, reads as follows:

"A nonprofit corporation may be formed under this article for the purposes of defraying or assuming the cost of professional services of licentiates under any chapter of Division 2 of the Business and Professions Code or of rendering any such services, but it may not engage directly or indirectly in the performance of the corporate purposes or objects unless:

"(1) At least one fourth of all licentiates of the particular profession become members;

"(2) Membership in the corporation and an opportunity to render professional services upon a uniform basis is available to all licensed members of the particular profession;

"(3) Voting by proxy and cumulative voting are prohibited; and

"(4) A certificate has been issued to the corporation by the particular professional board, whose licentiates have become members, finding compliance with the foregoing requirements.

"Any such nonprofit corporation shall be subject to supervision by the particular professional board under which its members are licensed and shall also be subject to the provisions of Section 605c of this code. . . ." [The section 605c mentioned provides for supervision by the attorney general of the conduct of a nonprofit corporation holding property subject to any public or charitable trust.]

of St. Francis v. *Guillaume's Estate*, 222 Ill. App. 543, and *Stern* v. *Rosenthal*, 71 Misc. 422, 128 N. Y. S. 711. In *Jordan* v. *Group Health Ass'n*, 71 App. D. C. 38, 107 F. (2d) 239, a declaratory judgment was sought against the insurance commissioner of the District of Columbia to determine whether the activities of the association were subject to the supervision of the insurance commissioner. The Group Health Association was a nonprofit corporation organized to provide without profit medical services, surgery and hospitalization for its members. Its membership was limited to civil service employees of the executive branch of the federal government. In holding that the Group Health Association was not engaged in the insurance business the Circuit Court of Appeals for the District of Columbia had this to say:

> Although Group Health's activities may be considered in one aspect as creating security against loss from illness or accident, more truly they constitute the quantity purchase of well rounded, continuous medical service by its members. Group Health is in fact and in function a consumer cooperative. The functions of such an organization are not identical with those of insurance or indemnity companies. The latter are concerned primarily, if not exclusively, with risk and the consequences of its descent, not with service, or its extension in kind, quantity or distribution; with the unusual occurrence, not the daily routine of living. Hazard is predominant. On the other hand, the cooperative is concerned principally with getting service rendered to its members and doing so at lower prices made possible by quantity purchasing and economies in operation. Its primary purpose is to reduce the cost rather than the risk of medical care; to broaden the service to the individual in kind and quantity; to enlarge the number receiving it; to regularize it as an everyday incident of living, like purchasing food and clothing or oil and gas, rather than merely protecting against the financial loss caused by extraordinary and unusual occurrences, such as death, disaster at sea, fire and tornado. It is, in this instance to take care of colds, ordinary aches and pains, minor ills and all the temporary bodily discomforts as well as the more serious and unusual illnesses. To summarize, the distinctive features of the cooperative are the rendering of service, its extension, the bringing of physician and patient together, the preventive features, the regularization of service as well as payment, the substantial reduction in cost by quantity purchasing, in short, getting the medical job done and paid for, not, except incidentally to these features, the indemnification for cost after the service is rendered. Except the last, these are not distinctive or generally characteristic of the insurance arrangement. There is, therefore, a substantial difference between contracting in this way for the rendering of service, even on the contingency that it be needed, and contracting merely to stand its cost when or after it is rendered . . . But obviously it was not the purpose of the insurance statutes to regulate all arrangements for assumption or distribution of risk. That view would cause them to engulf practically all contracts, particularly conditional sales and contingent service agreements. The fallacy is in looking only at the risk element to the exclusion of all others present or their subordination to it. The question turns, not on whether risk is involved or assumed, but on whether that or something else to which it is related in the particular plan is its principal object and purpose.

We find in that case the express admission 71 App. D. C. at page 47 (107 F. (2d) at page 248) "that the identical plan and service rendered here would not be 'insurance' or 'indemnity' if offered by an organization owned, operated and controlled by physicians. It would then be a contract 'for service on contingency,' though the same element of risk and avoidance of its possible consequences would be present." Other authorities giving support to these views, in the court's opinion, were *State* v. *Universal Service Agency*, 87 Wash. 413, 151 P. 768, Ann. Cas. 1916C, 1017, supra; and *Commissioner of Bank and Insurance* v. *Community Health Service*, 129 N. J. L. 427, 30 A. (2d) 44.

There is no essential difference, concluded the court, between the Group Health Association, the San Francisco Health Service and California Physicians' Service except that in the first two the administrative management is in a board selected by the beneficiary members, whereas in the latter it is in a board selected by the professional members. All are nonprofit, semi-charitable organizations conducted for the primary purpose of affording necessary medical care to those of small income. None are organized to insure good health or freedom from disease. We are satisfied that on the authorities cited it must be held that California Physicians' Service is not engaged in the insurance business and is not subject to the supervision of the commissioner under the Insurance Code.

The declaratory judgment in favor of California Physicians' Service was, in effect, affirmed.—*California Physicians' Service* v. *Garrison*, 155 P. (2d) 885 (Calif., 1945).

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in THE JOURNAL, May 12, page 153.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Montgomery, June 26-28. Sec., Dr. B. T. Austin, 519 Dexter Ave., Montgomery 4.

ALASKA. Juneau, September. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

ARIZONA.* Phoenix, July 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS:* *Eclectic.* Little Rock, June 7. Sec., Dr. C. H. Young, 1415 Main St., Little Rock. *Medical.* Little Rock, June 7-8. Sec., Dr. D. L. Owens, 701 Main St., Little Rock.

CALIFORNIA: *Oral.* San Francisco, May 20. *Written.* San Francisco, July 9-12. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

COLORADO.* Denver, July 3-7. Final date for filing application is June 18. Sec., Dr. J. B. Davis, 831 Republic Bldg., Denver.

CONNECTICUT:* *Homeopathic.* New Haven, July 10-11. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven. *Medical Examination.* New Haven, July 10-11. *Endorsement.* New Haven, July 24. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE. *Examination.* Dover, July 10-12. *Reciprocity.* Dover, July 17. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA:* *Reciprocity.* Washington, June 11. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington 1.

FLORIDA:* Jacksonville, June 25-26. Sec., Dr. Harold D. Van Schaick, 2736 S. W. Seventh Ave., Miami 36.

IDAHO: Boise, July 10. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

ILLINOIS: Chicago, June 26-28. Superintendent of Registration, Department of Registration and Education, Mr. Philip Harman, Springfield.

INDIANA: Indianapolis, Aug. 28-30. Sec., Board of Medical Registration & Examination, Dr. W. C. Moore, 301 State House, Indianapolis 4.

KANSAS: Kansas City, June 28-29. Sec., Board of Medical Registration & Examination, Dr. J. T. Hassig, 905 N. Seventh St., Kansas City 10.

KENTUCKY: Louisville, June 18-20. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

LOUISIANA: June. Sec., Dr. R. B. Harrison, 1507 Hibernia Bank Bldg., New Orleans 12.

MARYLAND: *Medical.* Baltimore, June 19-22. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore. *Homeopathic.* Baltimore, June 19-20. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, July 10-13. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F. State House, Boston.

MICHIGAN:* Detroit, June 26-28. Sec., Board of Registration in Medicine, Dr. J. E. McIntyre, 100 W. Allegan St., Lansing 8.

MINNESOTA:* Minneapolis, June 19-21. Sec., Dr. J. J. DuBois, 230 Lowry Medical Arts Bldg., St. Paul 2.

MISSISSIPPI: Jackson, June 25-26. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson 113.

MISSOURI: St. Louis, June 7-9. Sec., State Board of Health, Miss Erma E. Nixon, State Capitol Bldg., Jefferson City.

MONTANA: Helena. Oct. 1-3. Sec., Dr. O. G. Klein, First Nat'l. Bank Bldg., Helena.

NEW JERSEY. Trenton, June 19-20. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.

NORTH DAKOTA: Grand Forks, July 3. Sec., Dr. G. M. Williamson, 415 S. Third St., Grand Forks.

OHIO: *Endorsement.* Columbus, July. *Examination.* Columbus, June 18-21. Sec., Dr. H. M. Platter, 21 W. Broad St., Columbus.

OKLAHOMA.* Oklahoma City, June 14-16. Sec., Dr. J. D. Osborn, Jr., Frederick.

SOUTH CAROLINA: Columbia, June 25-27. Sec., Dr. N. B. Heyward, 1329 Blandina St., Columbia.

SOUTH DAKOTA:* Pierre, July 17-18. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, State Capitol, Pierre.

TEXAS: Galveston, June 4-6. Sec., Dr. T. J. Crowe, 918-20 Texas Bank Bldg., Dallas 2.

VERMONT: Burlington, June. Sec., Dr. F. J. Lawliss, Richford.

VIRGINIA:* Richmond, June 20-23. Sec., Dr. J. W. Preston, 30½ Franklin Rd., Roanoke.

WASHINGTON:* Seattle, July 16-18. Sec., Department of Licenses, Miss Nell Adams, Olympia.

WEST VIRGINIA. Charleston, July 5-7. Commissioner, Public Health Council, Dr. John E. Offner, State Capitol, Charleston 5.

WISCONSIN.* Milwaukee, June 26-28. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

WYOMING. Cheyenne, June 4-5. Sec., Dr. G. M. Anderson, Capitol Bldg., Cheyenne.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

COLORADO: Denver, June 6-7. Sec., Dr. Esther B. Starks, 1459 Ogden St., Denver.

CONNECTICUT: June 9. Address State Board of Healing Arts, 250 Church St., New Haven 10.

FLORIDA: DeLand, June 1. Final date for filing application is May 17. Sec., Dr. J. T. Conn, John B. Stetson University, DeLand.

MINNESOTA: Minneapolis, June 5-6. Sec., Dr. J. C. McKinley, 126 Millard Hall, University of Minnesota, Minneapolis 14.

OREGON: Portland, July 7. Sec., Mr. C. D. Byrne, University of Oregon, Eugene.

SOUTH DAKOTA: Yankton, June 19. Sec., Dr. G. M. Evans, Yankton.

Council on Medical Education and Hospitals

HOSPITAL MEDICAL LIBRARY SUGGESTIONS

Prepared by the Council on Medical Education and Hospitals of the American Medical Association

An adequate library is essential in hospitals that undertake an educational function. To interns and resident physicians it is especially important as a source of immediate reference in the study of diagnostic and therapeutic problems and in the preparation of reports for staff meetings and clinical conferences. Indeed, to all physicians a medical library plays a significant part in the continuation of their education.

"A medical group which works with little or no reference to books and journals suffers serious limitations. Without knowledge of what others have discovered, daily experience cannot be resourcefully interpreted. Avoidable mistakes, waste and duplication of effort are inevitable. Doctors become victims of empiricism and routine; imagination and initiative lack stimulus; enthusiasm and energy decline; minds grow sterile that under the quickening influence of the recorded experience of others might have been fruitful." [1]

The following are the minimum needs of a reference library as expressed in the Essentials of an Approved Internship:

"There should be a medical library, in charge of a competent librarian, located where it is readily accessible to the interns and staff and containing a useful collection of recent editions of standard text and reference books and current files of not less than ten of the representative medical journals. Interns should be encouraged to use the library in connection with their clinical work and may properly be asked to report on current medical opinion concerning any special case at the bedside or to review current literature on any selected topic more formally at staff conferences or at journal club meetings that may be organized for the purpose of stimulating an interest in reading."

Similarly in the Essentials of Approved Residencies and Fellowships it is stated that "institutions offering graduate training should maintain or provide ready access to an adequate medical library containing modern texts, the *Quarterly Cumulative Index Medicus* and current journals relating to the fields in which residencies and fellowships are offered."

These standards serve as a guide to the establishment of a working library for the house staff where material will be available for general reference. For special needs it is usually possible to obtain additional material from outside sources.

ORGANIZATION

The usefulness of a medical library depends largely on its accessibility, the scope and quality of reference material, and the ability of the librarian and the staff to stimulate an interest in the review of medical literature. It is especially important that the medical staff should take an active interest in the development and maintenance of a suitable library, its financial support, technical supervision, the selection of books and periodicals, and the establishment of appropriate rules and regulations.

A committee of the staff should be appointed to maintain general supervision. Technical direction, however, can be assigned to a librarian who has had adequate training and experience in this work. In the absence of an experienced librarian a competent person from the record department or administrative personnel could be placed in charge.

The medical library is of sufficient importance in the educational scheme to justify the annual budgeting of funds for this purpose. Ordinarily it would require from $300 to $500 to establish a satisfactory nucleus of reference material for the house staff. By the gradual addition of books and periodicals from year to year a library would be evolved that could be considered an asset to the institution and the community. The annual expenditure would vary in accordance with the amount of reference material supplied, but usually it would require a minimum of $150 to $300 to provide the necessary books and journals.

When funds are not furnished through gifts, endowments or the operating budget, it may be possible to maintain the library by annual contributions from the attending physicians. These funds might then be collected in the form of staff dues.

LOCATION

It would be worth while for those interested in developing a medical library to visit similar departments and study the elements that contribute to their success. Any well organized library, general or medical, would furnish valuable suggestions concerning space and equipment, classification of subjects, indexing, and methods of filing, binding and storage.

The location of the medical library will in a large measure determine its usefulness. If it is readily accessible, comfortable and attractive, it will soon become the center of interest of the house staff. The library is most frequently found in the administrative section of the hospital near the record department or staff room, but other locations will also prove satisfactory if adequate organization and supervision are maintained. The room should be sufficiently large to house books, periodicals, reprints and other material without encroaching on the space needed for comfortable reading and uninterrupted study.

REFERENCE MATERIAL

In establishing a medical library, it is well to purchase only a few reference books on each subject. Only recent volumes should be chosen, with the exception of such standard works as are recognized classics in their respective fields and do not rapidly become obsolete. The literature on therapy and diagnosis, for example, is changing with such rapidity that the use of the most recent publications is recommended. In the field of fundamental sciences, such as anatomy and histology, literature is more stabilized and longer lived. More recent editions of the standard textbooks should be added from time to time, thus keeping the library up to date with regard to new methods of diagnosis and treatment. After a good foundation has been formed, the remainder of the apportioned funds may be expended in purchasing varied reference works that are known to be of particular value. The library should not be allowed to become a depository for antiques, and out of date books should be removed or discarded.

1. Dr. George E. Vincent, speaking on the occasion of the celebration of the fiftieth anniversary of the Boston Medical Library, Jan. 19, 1926.

The usefulness and efficiency of the hospital medical library depend not only on a good selection of medical books but also on a well chosen group of periodicals Limited library funds are often more usefully expended for periodicals than for text and reference books When ample funds are provided there is no great difficulty experienced in the selection of material

The hospital library may supplement its service by the use of the library facilities of nearby medical schools, the academy of medicine or the local county medical society It may also utilize the package library of the American Medical Association This consists of collections of reprints and other material on various subjects, prepared for lending to members of the Association and to individual subscribers to publications of the American Medical Association Information on the loan systems of medical school libraries or society libraries can readily be obtained on inquiry.

SUGGESTED PERIODICALS

The following list is furnished as a guide to the selection of medical periodicals in accordance with the needs of individual hospitals In view of the interrelation of the various fields of medicine it is desirable that a wide selection be made to cover both general and special subjects To accomplish this a minimum of ten periodicals would ordinarily be required No attempt has been made to include all of the useful journals in the various fields; only a few have been selected which it is believed the average general hospital would find particularly desirable For a complete list of periodicals, both domestic and foreign, reference should be made to the *Quarterly Cumulative Index Medicus*

ANESTHESIOLOGY

Anesthesiology Business Manager, Dr William G Schmidt 235 N 15th St Philadelphia Bi M $6

UROLOGY

Journal of Urology. Williams & Wilkins Company, Mount Royal and Guilford Aves., Baltimroe 2. M. $10.

SUGGESTED BOOKS

The books mentioned in the following list are suggested as a guide for hospital medical libraries. The list is not in any sense complete but should serve to indicate the type of books ordinarily required in the organization of educational services for interns and resident physicians. The *Quarterly Cumulative Index Medicus,* medical publishers' lists, the Book Notices section of THE JOURNAL and other sources of information can also be utilized in the selection of suitable hospital reference material. Modern medical practice is constantly changing and it is therefore recommended that hospital medical libraries adopt a policy of constantly replacing older medical textbooks with those which are new and up to date. In accordance with this principle the books included in this list, with few exceptions, have appeared for the first time or in revised editions since 1940. The names and addresses of the publishers appear at the end of the list of books.

ANATOMY

Bailey, F. R.: Text-Book of Histology. Ed. 11, ed. by Philip E. Smith. $6. Wood, 1944.
Beesly, L., and Johnston, T. B.: Manual of Surgical Anatomy. Ed. 5, rev. by J. Bruce and R. Walmsley. $6.50. Oxford, 1939.
Callander, C. Latimer: Surgical Anatomy. Ed. 2. $10. Saunders, 1939.
Cowdry, E. V.: Textbook of Histology. Ed. 3. $7. Lea, 1944.
Cunningham, Daniel J.: Text-Book of Anatomy. Ed. 8, ed. by J. C. Brash and E. B. Jamieson. $12. Oxford, 1943.
Grant, J. C. B.: Atlas of Anatomy. $10. Williams and Wilkins, 1944.
Gray, Henry: Anatomy of the Human Body. Ed. 24, rev. and ed. by Warren H. Lewis and others. $12. Lea, 1942.
Jordan, H. E., and Kindred, J. E.: Textbook of Embryology. Ed. 4. $6.75. *Appleton, 1942.*
Krieg, Wendell J. S.: Functional Neuroanatomy. $6.50. Blakiston, 1942.
Maksimov, A. A., and Bloom, W.: Textbook of Histology. Ed. 4. $7. Saunders, 1942.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama State Medical Assn. Journal, Montgomery

14:181-208 (Feb.) 1945

Bronchiectasis. J. O. Lisenby.—p. 181.
Planning for Medical Care in Postwar Period with Particular Reference to Alabama. J. Newdorp.—p. 183.
Value of Preemployment Examination in Industrial Health Program. P. W. Auston.—p. 189.
Management of Complications of Intraocular Surgery. H. W. Frank.—p. 193.

14:209-232 (March) 1945

Total versus Subtotal Hysterectomy. J. O. Morgan.—p. 209.
Planning for Medical Care in Postwar Period, with Particular Reference to Alabama: Part II. J. Newdorp.—p. 213.
What Surgeon Should Know of Radiology in Treating Malignancy. I. P. Levi.—p. 219.

Amer. Journal of Digestive Diseases, Fort Wayne, Ind.

12:61-96 (March) 1945

Orientation of Gastroscope by Roentgenograms. A. R. Hufford and G. G. Stonehouse.—p. 61.
Aluminum Phosphate Gel in Treatment of Peptic Ulcer. J. Lichstein, S. Simkins and M. Bernstein.—p. 65.
Bacillary Dysentery in Curaçao, Netherlands West Idies. A. W. Pot.—p. 70.
Gastrointestinal Disorders Simulating Circulatory Disease and Vice Versa. F. M. Groedel.—p. 73.

Arterial Thrombosis Associated with Chronic Ulcerative Colitis. Mary E. Martin.—p. 85.

Am. J. Roentgenol. & Rad. Therapy, Springfield, Ill.

53:109-212 (Feb.) 1945

Roentgenologic Appearance and Pathology of Intrapulmonary Lymphatic Spread of Metastatic Cancer. H. P. Mueller and R. C. Sniffen.—p. 109.
Pulmonary Changes in Cardiospasm. L. E. Hawes and A. B. Soule Jr.—p. 124.
Congenital Aplasia of Lung. R. L. Garber.—p. 129.
Acute Obstruction of Colon: Differential Diagnosis Between Volvulus and Cancer of Sigmoid Colon by Preliminary Roentgenogram. J. Levitin and H. B. Weyrauch.—p. 132.
Meckel's Diverticulum. M. E. Mottram and L. H. Garland.—p. 142.
*Periosteal Lesions in Scurvy. W. A. Evans Jr.—p. 147.
Roentgenographic Demonstration by Tantalum Powder of Sinuses Resulting from Extraction of Intervertebral Disk Protrusions. C. J. Graf and W. B. Hamby.—p. 157.
Anomalous Development of First Rib Simulating Isolated Fracture. E. R. Bowie and H. G. Jacobson.—p. 161.
Triticeous Cartilages: Roentgen Anatomic Study. J. W. Grossman.—p. 166.
Changes After Treatment of Unprotected Brain with Large Doses of Roentgen Radiation. O. Marburg, R. Rezek and R. M. Fleming.—p. 171.

Periosteal Lesions in Scurvy.—Evans reviewed roentgenograms of cases in which the diagnosis of scurvy had been made at the Children's Hospital of Michigan during the years 1936 to 1941. During this six year period in a hospital service comprising 106,800 new outpatient visits and 41,773 hospital admissions 93 cases were encountered, indicating that even in these days of vitamin consciousness infantile scurvy is not rare. It occurs almost exclusively in the narrow age range of 7 to 15 months. The most advanced lesions were usually seen in the knees, followed by the shoulder and ankle joints, and then by the wrist, hips and elbow joints. The earliest changes represented by the ground glass type of demineralization of the bone structure and by the signet ring appearance of the epiphyses are seen with great frequency but are not of sufficient specificity to be regarded as pathognomonic of scurvy. The signet ring appearance was most pronounced in the epiphyses at the knee joints and was present in the same degree in all of the cases. The ground glass appearance was seen less constantly (74 per cent) and was absent particularly in cases complicated by rickets. The submetaphysial notch, emphasized by Park and his colleagues as the earliest pathognomonic sign of scurvy in the x-ray examination, was observed in 89 per cent of the 93 cases. Periosteal shadows in scurvy were observed to be of two types. The first appears as a narrow triangular shadow having its base at the metaphysis and extending from there for some distance along the shaft. The second type of periosteal shadow is much larger, is usually club shaped and extends along the greater length of the shaft. The periosteal lesions of scurvy depend for their occurrence, location and severity on the severity of the lesions which develop in the metaphysial areas of the long bones.

Annals of Allergy, Minneapolis

3:1-90 (Jan.-Feb.) 1945

Growth and Development of Allergy: Ten Year Study of 100 Allergic Children from Birth to 10 Years of Age. N. W. Clein.—p. 1.

Skin Graft of Dorsum of Hand: Use of Large Size Dermatome to Obtain One Piece Pattern. J. M. Converse.—p. 172.
Proximal Ligation and Thrombectomy for Phlebothrombosis of Femoral and Iliac Veins. F. W. Bancroft.—p. 175.
Economic Value of Peritoneoscopy. M. M. Narancio, J. C. Pierson, G. McNeer and G. T. Pack.—p. 185.
Spontaneous Intra-Abdominal Hemorrhage. M. Marks and S. O. Freedlander.—p. 191.
Comparative Studies of Cancerous versus Noncancerous Breasts. F. W. Foote and F. W. Stewart.—p. 197.
Studies in Surgical Convalescence: II. Preliminary Study of Nitrogen Loss in Exudates in Surgical Conditions. Co Tui, A. M. Wright, J. H. Mulholland, E. S. Breed, I. Baicham and D. Gould.—p. 223.
Effects of Temperature on Digestion of Collagen Sutures and Surgical Gut (Catgut) by Enzymes and by Subcutaneous Tissues of Frog. I. W. Sizer.—p. 231.
Submucosal Morcellation of Hemorrhoids. H. B. Benjamin, H. W. Ahrenberger and C. J. Fairless.—p. 239.
Albright's Syndrome: Report of Case Associated with Multiple Pathologic Fractures, Disseminated Fibrous Dysplasia of Bones, Precocious Puberty and Multiple Pigmented Nevi. A. Behrend.—p. 245.

Biopsy as Guide to Early Skin Grafting.—Pritchard says that in burns it is desirable to have some means of determining whether the wound can be expected to heal spontaneously or whether it should be skin grafted. At the Montreal General Hospital the treatment of burns includes the occlusive compression dressing with an emulsion of sulfathiazole in an oil in water base. This dressing, except in superficial burns which heal within one week, is commonly removed on about the thirteenth or fourteenth day, with the intention of grafting if necessary. It is not easy, even at this stage, to be certain from the gross appearance of the wound whether it is healing satisfactorily or will require grafting. It was decided to submit all questionable cases at the time of removal of the first dressing to biopsy. Rapid frozen sections were relied on. If destruction involves most or all of the hair follicles but spares the sweat glands which lie at a deeper level, spontaneous reepidermization may still be expected, but the process will be slow.

If the destruction extends deep enough to involve the sweat glands there will be no sources of reepidermization other than that at the margins of the wound, and this, in all but small burned areas, is inadequate.

Divergence Paralysis and Head Trauma. N. Savitsky and M. J. Madonick.—p. 135.

**Electroencephalographic Evaluation of Primary Behavior Disorders in Children: Correlations with Age, Sex, Family History and Antecedent Illness or Injury.* J. S. Gottlieb, J. R. Knott and M. C. Ashby.—p. 138.

Subdural Suppuration Originating in Purulent Leptomeningitis. E. Spitz, Ann Pollak and A. Angrist.—p. 144.

Hyperthermia Following Injury of Preoptic Region: Report of Case. L. E. Beaton and J. D. Herrmann.—p. 150.

Prefrontal Lobotomy in Chronic Psychoses.—Hofstatter and his associates performed prefrontal lobotomy on 45 patients. Thirty of these were studied for twelve months or more after the operation. Of these 8 had been subjected to the unmodified operation and 22 to the section of the orbital area only. None of the patients became worse after the operation. None died. Transitory incontinence occurred in 4 of the 22 patients in whom only the lower quadrants were sectioned and in 4 of the 8 patients in whom all quadrants were transected. Delusional ideas might disappear rapidly or might continue with less emotional impetus than before. During the period of convalescence the patient's psychotic behavior persisted to some extent; then inertia became more prominent. The postoperative rate of recovery of 40 per cent of the total number of patients compares favorably with the computed average of 31.3 per cent of seventeen other American centers. The results of surgical intervention on only the orbital quadrants in these patients appear at least equal to the results obtained with transection of all four quadrants. The orbital areas of the frontal lobes seem to have a role in regulation of the emotions.

Electroencephalographic Evaluation of Behavior Disorders.—Gottlieb and his associates show that there is a high incidence of abnormality in the electroencephalograms of children with primary behavior disorders. In a series of 67 children, none of whom presented signs of organic disease or in whose condition an organic etiologic factor was suspected, 49 per cent had electrical brain potentials which were clearly abnormal. Significantly, greater proportions of abnormal electroencephalograms were found when there was either a history of psychosis, maladjusted personality, chronic alcoholism or epilepsy in the family or a personal history of cerebral trauma or severe illness than when neither of these factors was present.

Simple Technic for Corneal Transplantation. M. I. Green.—p. 150.

Industrial Injuries of Eye Caused by Flying Objects. P. W. Tisher.—p. 152.

Retinal Changes in Diabetes and Hypertension.—Ballantyne maintains that the retinopathies of diabetes and of the hypertensive diseases are separate entities. In both conditions the earliest lesions are changes in the retinal vessels. In diabetes these lesions affect primarily the venous, and in hypertension the arterial, side of the retinal circulation. In diabetes these changes point to venous stasis and, in addition to hemorrhages and exudates, consist in congestion of the veins, microaneurysms of the capillaries and gross changes in the principal veins. Microaneurysms seem to be the earliest pathologic change in the fundus of the diabetic patient. Histologically the earliest recognizable change takes the form of minute fatty granules in the vascular endothelium, together with swelling of the endothelial cells. In hypertension fatty granules are observed more frequently in the media and the adventitia. The most striking changes in the retinal veins of diabetic patients appear as expansions, beading and formation of loops, coils and networks, and the predominant microscopic changes at this stage are phlebosclerosis and intraretinal and preretinal networks of large, thin walled vessels. The hemorrhages in diabetic retinopathy occur primarily in the central area of the fundus, are characteristically rounded and occur chiefly in the deep layers, for the most part the internuclear layer. In hypertension arterial changes predominate; the hemorrhages are primarily circumpapillary and striate, owing to their situation in the nerve fiber layer. Exudates are observed in the deep layers but also include patches of gangliform degeneration in the nerve fiber layer.

Experimental Nephropathies: I. Method of Producing Controlled Selective Injury of Renal Units by Means of Chemical Agents. J. P. Simonds and Opal E. Hepler.—*p. 103.*

Congenital Glycogenic Tumors of Heart.—According to Batchelor and Maun, congenital tumors of the heart are comparatively rare. In the case reported glycogen was demonstrated within the tumor cells of the multiple tumors of the heart of an infant who died on the third day of life. A review of the literature on so-called congenital rhabdomyoma of the heart revealed 62 authentic cases of tumors of the heart that presented a characteristic vacuolated appearance on microscopic examination. The cardiac tumors were seen chiefly in infants and the newborn, with 52 per cent of the patients dying in the first year of life and 86 per cent before they reached puberty. The clinical symptoms were nonspecific, and in no case was the diagnosis made before death. Frequently the symptoms were due to associated lesions. Tuberous sclerosis was found in 50 per cent of the cases. The authors suggest that the term "congenital nodular glycogenic tumors of the heart" should replace "congenital rhabdomyoma" until more is known about the nature of the lesions.

Primary Tumor of Heart.—Strauss and Merliss present 3 additional cases of primary tumor of the heart, 2 of which were instances of myxoma and 1 of myxosarcoma. In 2 the tumor was silent, in the third it produced clinical signs and symptoms of tricuspid stenosis. As a rule, primary tumor of the heart is clinically silent. Only 2 cases are on record which were diagnosed prior to death. In both the tumor was a cancer involving the conduction system and in both there was a hemorrhagic pericardial effusion. In no case of benign tumor has the diagnosis been made before death. Primary tumor of the heart should be considered in the differential diagnosis when there is sudden onset of signs of cardiac decompensation in a young person without a preexisting history of heart disease with no discoverable anatomic basis for the heart disease, a hemorrhagic pericardial effusion, an involvement of valvular function or of the conduction system and signs of valvular stenosis which change on motion of the body as well as signs of mediastinal tumor with alteration of the appearance of the shape of the heart in the roentgenogram.

Inspection of Oysters.—Snook states that oysters contain both protein and carbohydrates When these decompose, fermentation as well as putrefaction occurs Following the death of the oyster, which occurs soon after shucking, the glycogen is hydrolyzed to produce sugars, which in turn are fermented by bacteria to produce acid Acid production is gradual, and a direct relation exists between hydrogen ion concentration and the stage of decomposition. The edibility of oysters can be determined readily by the use of p_H tests Freshly shucked oysters normally show a p_H of between 6 3 and 7.1. When the p_H drops to between 5.7 and 5.9 the oysters are considered "stale," and when a p_H below 5.7 is reached they are considered "sour." The edible zone is thus above a p_H of 5 9. If oysters are kept under proper refrigeration, the lower limit of the edible zone, that is, a p_H of 5.9, is reached about eleven days after shucking. For reliable p_H readings it is advisable to use the Taylor slide comparator, a La Motte block comparator or a potentiometer. Nitrazine paper should not be used. Milky liquor is a normal property of oysters, but when in doubt a p_H reading is necessary. The only satisfactory method of preventing spoilage of freshly shucked oysters is the liberal use of ice. Green oysters should not be rejected. This condition is caused by the accumulation in the gills and mantle of the oyster of a bluish or greenish pigment derived from certain types of diatoms which normally live in sea water and are ingested by the oyster. Pink oysters are stale.

*Errors in Applying Nutrient Allowances to Dietary Surveys or Food Policies L B Pett —p 69.

Nutrient Allowances in Food Policies.—Pett shows that innumerable combinations of individual foodstuffs are capable of providing optimal nutrition. This is fortunate because it permits adaptation to the wide variations observed around the world in dietary habits, in agricultural possibilities and in food composition Standards have been devised from time to time. The most detailed of such tables is that of the United States National Research Council drawn up in 1941-1942 Serious errors may result when attempts are made to interpret such standards in terms of foods and in terms of national and international food requirements and agricultural policies. Physiologic experiments show a variation in individual susceptibility or requirements. Out of 97 persons a balance between intake and output of calcium was achieved for 22 persons with less than 0 35 Gm. daily, while 54 persons were in balance with between 0 35 and 0 55 Gm of calcium daily, and 3 needed over 0.70 Gm. daily. The mean or average for this group is between 0.40 and 0 45 Gm. of calcium daily. In order to allow for unknown factors, the recommended allowance in the standard is 0 8 Gm. Only a small fraction of a population group needs this much; nearly half of the group could be in calcium balance with a calcium intake of only 50 per cent of the standard. Standards are also used as points of reference for dietary surveys. Current efforts to plan national or international food policies may lead to serious errors unless account is taken of the lack of knowledge on how to apply "standards" or "requirements" for various nutrients to population groups.

Effect of Succinylsulfathiazole and Phthalylsulfathiazole on Bacterial Flora of Rat Feces. A. Kathrine Miller.—p 143

Environment and Ascorbic Acid Content of Tomatoes.—Hamner and his associates studied the influence of environmental variables on the ascorbic acid content of tomatoes in the field and under controlled conditions in the laboratory. Neither the nature of the soil nor fertilization has been found to exert a great effect. There is also little evidence that the location effects can be ascribed to differences in temperature, humidity or variations in day length. The one variable so far studied which seems to exercise great effects is light intensity. Greatest influence on ascorbic acid content was produced by variations in light intensity previous to harvest. Increases in the ripe fruit of 66 per cent in ascorbic acid resulted when plants were transferred from shade to sunshine at the time the fruit was mature green The light intensity to which the plants are exposed just previous to harvest may be the dominant factor in determining the ascorbic acid content of ripe fruit.

Duodenal Drainage in Steatorrheas.—According to Philipsborn and his associates fibrocystic disease of the pancreas and celiac disease may resemble each other closely. Fibrocystic disease is characterized by an achylia or hypochylia

pancreatica. Celiac disease is considered a failure of absorption of already digested foodstuffs. Since the stools in celiac and fibrocystic disease may be identical and because the vitamin A curve is diagnostically nonspecific, quantitative analysis of the duodenal drainage for enzymatic activity coupled with a notation of the response of the pancreas to secretin or intraduodenal hydrochloric acid is the most reliable laboratory aid in the differential diagnosis of fibrocystic and celiac disease. "Feeding problems" may be on the basis of a temporary pancreatic insufficiency. Permanent pancreatic insufficiency with infantilism must be differentiated from celiac disease, fibrocystic disease and certain types of feeding problems. The value for tryptic activity is the most reliable index of pancreatic function. Values of less than 4 Gm. of liberated nitrogen per hundred cubic centimeters of duodenal fluid are abnormal in children. Less than 0.5 Gm. of liberated dextrose per hundred cubic centimeters of duodenal drainage during the first twelve months of life is abnormal. Subsequently less than 2 Gm. of liberated dextrose is abnormal in children. When less than 60 cc. of twentieth normal sodium hydroxide is required to neutralize the free fatty acids produced by the lipolytic activity of 100 cc. of duodenal fluid the pancreatic lipase may be considered diminished in children. The enzymatic activity in the duodenal drainage is greatly diminished in fibrocystic disease; it remains essentially normal in celiac disease. The response to intravenous secretin or intraduodenal tenth normal hydrochloric acid is reduced in fibrocystic disease but may remain normal in celiac disease and in transient and permanent hypochylia pancreatica.

Calcification of Intervertebral Disks in Childhood.—Weens says that instances of calcification of the intervertebral disks have been observed in childhood. He reports 1 case that he observed and reviews 5 cases from the literature. Contrary to observations in adult life, prominent clinical signs and symptoms were noted. All of the cases were characterized by an acute episode of pain in the region of the involved segment of the spine, limitation of motion and spinal deformity. In the absence of pathologic studies it is not possible to arrive at definite conclusions as to the etiology of this phenomenon in childhood. Signs and symptoms of infection were noted in most of the cases, and these suggest that an inflammatory process was associated with the calcification. The fact that the intervertebral disks in childhood possess a blood supply may be important in this connection. The intervertebral disks are thus open to any disease carried by the blood stream. An aseptic necrotic process as a possible cause of the calcification is mentioned. The author stresses differences between calcification of intervertebral disks in childhood and in adult life. Involvement of the cervical spine was noted in 4 of 6 cases occurring in childhood. Calcification of the nucleus pulposus in adult life is localized predominantly in the dorsal spine and lumbar spine. Rapid change in the size of the calcification or complete absorption was noted in 5 of the 6 described cases. Calcification of the nucleus pulposus in adult life is, as a rule, a stationary process. All of the children recovered. The recognition of calcification of intervertebral disks in children appears important in view of the differential diagnosis of meningitis, myositis and diseases involving the vertebrae or spinal cord.

Lobectomy versus Thoracoplasty.—The evaluation of primary upper lobectomy and of selective thoracoplasty convinced Chamberlain that thoracoplasty is successful because it utilizes four of the five basic principles of therapy in tuberculosis: (1) drainage (bronchial), (2) immobility, (3) relaxation and (4) compression. The fifth principle, resection, is reserved for its failures. Primary upper lobectomy excises only the active major focus and causes overdistention, which is probably a precursor to emphysema, may cause reactivation of latent foci in the overdistended lobes and leaves these foci in a poor state of healing or self protection. Primary upper lobectomy may prove to be a less physiologic procedure than the modern selective six rib thoracoplasty, since the latter shows a significant reduction in function in only 25 per cent of the cases. Upper lobectomy should be secondary to the thoracoplasty failure.

Herniated Intervertebral Disk.—Poppen studied 400 surgically proved cases in which eighteen months to ten years have elapsed since surgical intervention. This series represents 8 per cent of the patients who entered the clinic with the complaint of low back pain. This emphasizes that even though the herniated disk is an important cause of low back pain and sciatica it is by no means the predominant one. The most constant objective finding was a positive straight leg reaction, which was present in 90 per cent of the patients when the protrusion was at the third, fourth or fifth lumbar segment. Seventy-five per cent of the patients demonstrated spasm of the low back muscles. Localized paraspinous tenderness was present in 80 per cent. Forty-eight per cent had sensory changes in the fifth lumbar or first sacral dermatomes or both. Narrowing of the disk space was not an assurance that a posterior dislocation of a disk was present. A normal roentgenogram of the low spine in the presence of a typical history and findings is an additional indication of the probable presence of a ruptured cartilage. A patient who has had repeated disabling attacks of sciatica necessitating narcotics and who in the previous few months has been unable to work because of a ruptured cartilage should have an operation. When a patient has had mild recurrences of symptoms causing considerable discomfort but not severe enough to discontinue work, he should be treated conservatively with physical measures in the form of heat, massage and postural exercises, rest in bed on a firm mattress and administration of large doses of vitamin B intravenously for a few days. Patients with predominating leg pain and with minor back difficulty whose roentgenograms show no bone changes should have only the disk removed, whereas for a patient who has predominating back pain, with abnormal facets and evidence of an unstable back, and who has to do hard manual labor, removal of the degenerated cartilage with fusion is indicated. There were no deaths or paralysis in any of the patients operated on. Infection occurred in 3 patients, but opening the incision and allowing adequate drainage with liberal use of the sulfonamide drugs brought about wound healing. The shortest postoperative stay in the hospital was four days and the longest five weeks; the average stay was twelve days. The relief of sciatica was satisfactory in most of the cases. Residual back discomfort on heavy lifting or sitting in a cramped position for many hours occurred in almost half the patients. This percentage was not materially altered in those who also had fusions. Fifteen per cent of patients did not obtain relief. Six cases in a series not treated surgically developed sudden complete paraplegia as a result of ruptured cartilage. Even though the protruded cartilages were removed in a relatively short time following the paralysis, many weeks and months elapsed before complete function returned.

Total Pancreatectomy, Gastrectomy, Duodenectomy, Splenectomy, Left Adrenalectomy and Omentectomy in Diabetic Patient.—Brunschwig and his associates report that a man aged 53 was admitted to a hospital with a complaint of watery, foamy stools for the previous two years and a loss of 50 pounds (23 Kg.). The presence of steatorrhea was confirmed and the patient was found to be severely diabetic. X-ray examinations of the stomach, duodenum, chest and colon were negative. Laparotomy was not indicated, as improvement occurred on medical management without pain. The patient was readmitted six months later because of moderately severe icterus, pruritus and pain in the right upper quadrant. Exploratory laparotomy revealed carcinoma of the body of the pancreas with invasion of the adjacent viscera. The patient was subjected to a total pancreatectomy, total gastrectomy, splenectomy, total duodenectomy and left adrenalectomy. The diabetes was not aggravated following the operation; there were periods when the diabetes appeared to be less severe than before operation. With a caloric intake equivalent to about 2,500 (400 Gm. of carbohydrate) the insulin requirements were 30 units of protamine and 10 units of regular insulin daily. Experience with this patient demonstrates the feasibility of very radical resections for abdominal cancer. Two and a half months after the operation the patient was in fair condition and ambulatory, but a month later he died and necropsy revealed abdominal carcinomatosis.

Malaria from Blood Transfusions.—Two patients were infected with blood that had been refrigerated for five days. A woman aged 57 developed malaria after a transfusion with bank blood, the donor having been a man aged 50 who had been born in Sicily and who at the age of 10 had had chills and fever for four months; he had been living in Michigan since the age of 16; an ordinary blood smear made on the donor after the transfusion was negative for malarial parasites. A white woman aged 23 developed malaria following transfusion of bank blood; her donor also had been a man born in Sicily, who had lived in this country since the age of 19. Since addition of quinine to the blood has been without effect, prophylactic administration of the drug to the recipient has been suggested, whenever questionable blood is being given. McClure and Lam state that the proper screening of donors is the logical means of preventing malarial transmission and that questions relating to geography would probably be more effective than those regarding past illness.

Absorption of Sulfonamides from Burn Surface.—Evans and his associates show that absorption of sulfonamides from a burn surface is limited when oil base ointments are employed. In contrast, when a water dispersible base is used toxic blood levels of the drug may occur. Studies on burned patients indicate that oil base sulfonamide ointments can be used with safety; their use has been attended with gratifying results of low incidence of infection. An oil base composed largely of mixtures of lanolin and petrolatum has proved very satisfactory.

Thrombosis of Deep Leg Veins.—Hunter and his associates present a comparative study of the incidence of venous thrombosis in the legs in 400 unselected necropsies on adults performed before and after preventive measures were instituted. In the first group the authors routinely removed the calf muscles in order to test their conviction that the most important etiologic factor in phlebothrombosis of the lower extremities is confinement to bed for more than a brief period. The second study was extended to include dissection of the femoral veins and those of the abductor muscles, shown by Frykholm to be almost as frequently occluded as the major veins. The authors found that phlebothrombosis of the lower extremities begins in the deep vessels of the calf and tends to propagate toward the heart, and that thrombosis of the femoral veins alone is an uncommon occurrence. Thrombosis of the deep veins of the leg is a frequent event in all classes of middle aged and older patients who must go to bed for longer than a few days. The onset is insidious and without prominent symptoms. Phlebitis, as a cause or as a complication of deep extremity vein thrombosis, is uncommon and for this reason is unimportant. The logical approach to the problem of phlebothrombosis and pulmonary embolism is prophylactic. The authors stress the importance of leg exercises after operations and in other bedfast patients. Reeducation of physicians and nurses with respect to the causes of thrombosis of the legs is urgently needed. The incidence of phlebothrombosis in medical patients proved to be significantly less than it was in the first 200 cases. It seems probable that the institution of active exercises for this group is responsible for the decrease.

Dicumarol in Prevention of Postoperative Thrombosis and Embolism.—One thousand surgical patients were given dicumarol in the immediate postoperative period for the purpose of preventing postoperative venous thrombosis, pulmonary embolism and thrombophlebitis. Barker and his associates have found it effective in preventing these complications in cases in which there had been nonfatal pulmonary embolism, thrombophlebitis or a history of previous thrombosis or embolism and when the drug was given prophylactically if no thrombosis or embolism had occurred. There is a small risk of bleeding. This can be minimized by proper administration of the drug and rapid control of excessive prothrombin deficiency. Dicumarol should not be given unless prothrombin time tests are done daily. The prothrombin level should be kept between 10 and 30 per cent of normal. Excessive prothrombin deficiency produced by dicumarol can almost always be controlled by the intravenous administration of large doses (60 to 64 mg.) of menadione bisulfite (synthetic vitamin K). If bleeding occurs as the result of excessive prothrombin deficiency it can be controlled by transfusions of freshly drawn citrated blood and intravenous administration of large doses of menadione bisulfite.

Surgical Therapy of Thrombosis of Lower Extremities.—Fine and Starr show that heparin and dicumarol are useful but not thoroughly dependable agents for the prophylaxis of pulmonary embolism. Their use is furthermore complicated by hemorrhage in wounds and elsewhere, which has occasionally proved fatal. The surgical prophylaxis of pulmonary embolism is the procedure of choice among those who prefer a more direct and immediately applicable method for blocking the discharge of an embolus. The risks of ligation of the common femoral, the iliacs and possibly also the vena cava are minimal and are accompanied by little postoperative disturbance except for transitory increase in edema in occasional instances. The selection of the level of ligation is made on the basis of the extent of involvement: (*a*) The common femoral vein is ligated when thrombophlebitis is limited to the veins below the knee or when pulmonary embolism has occurred in the absence of all signs of involvement; (*b*) the common iliac is ligated when thrombophlebitis involves the common femoral, external or common iliac veins; (*c*) the vena cava is ligated when the indications are that both common iliacs require ligation. Since the frequency of bilateral involvement is high, bilateral vein ligation is generally indicated. The occurrence of spastic narrowing or obliteration of venous channels limits the diagnostic usefulness of venography. The distinction between quiet venous thrombosis and full blown thrombophlebitis, that is, phlegmasia alba dolens or milk leg, is not a dependable means of deciding when a clot is detachable and when it is not. Therefore, exploration in most cases of so-called milk leg is advisable Early mobilization after operation does not provide full security against the development of thrombophlebitis.

Immersion Blast Injury.—Gage reports observations on 98 men who had survived a sinking at sea and subsequent depth charge explosion. Serious intra-abdominal injury occurred in 23 patients. Since these patients were received thirty-six hours after injury, conservative treatment was decided on. Morphine was given freely to overcome shock, to relieve pain and to reduce intestinal activity. No patient was given food or an enema until it could be determined that no intra-abdominal injury was present. Plasma, dextrose or saline solution was given as indicated. In 10 instances it was necessary to pass a Miller-Abbott or Wangensteen suction tube. At the end of ten days 35 of the 98 patients remained in the hospital, 58 had been discharged and 5 had died. Four of the deaths occurred in seven, twenty-seven, thirty and forty-two hours respectively, the cause being generalized peritonitis. At no time were these patients in condition for operation. The fifth death occurred at the end of five days from pooled plasma anaphylaxis. Nearly all the injured men reported that they felt as if they had been kicked in the painful area (stomach, back, testes) when the depth charge went off. All but 2 of the patients with serious abdominal injury estimated that they were within 100 feet of the depth charge when it went off. A study of the severe abdominal injuries shows that when the depth charge exploded all these men were on their abdomens or were in water above the abdomen and facing the blast. The advisability of allowing no food or activity until careful examination has been made cannot be overemphasized. Surgical intervention might have been deemed necessary in some instances had the patients been hospitalized within ten to twelve hours after the explosion. Secondary perforation of a viscus occurred in 2 patients, in 1 as late as forty days after the injury. One man who was promptly operated on recovered. Gage is inclined to believe that, with the excellent supportive treatment received, recovery might have occurred without operation. This does not mean that patients with immersion blast injuries with perforation, rescued early, should not be operated on; however, when the optimum period for operation has passed, nonoperative treatment can help save many lives.

Venopressor Mechanism in Shock: Treatment with Nikethamide.—According to Gunther peripheral circulatory failure is always associated with and preceded by a decline in intramuscular pressure. Shock, observed under these circumstances, is never manifest without a low intramuscular pressure. The value for intramuscular pressure may be found as low as 20 mm. of water. This level indicates a complete absence of muscle tonus and a complete failure of the venous pump An increase in intramuscular pressure, either spontaneously or induced by treatment, to above 40 mm. of water always coincides with compensation of a failing peripheral circulation Of the many substances studied, only two accomplished a restoration of a low intramuscular pressure. These were human plasma and a 25 per cent solution of pyridine-beta-carboxylic-acid-diethylamide, which is known as nikethamide. Human plasma acts slowly, requiring from seventy to one hundred minutes to manifest its pressor action on the venopressor mechanism Nikethamide acts rapidly, manifesting its pressor action on the venopressor mechanism within five to ten minutes, but the effect does not last as long as with plasma. The intravenous administration of nikethamide in adequate dosage will support the venopressor mechanism during the time needed for plasma to become effective. Nikethamide is to be used as an adjunct before or concurrently with plasma. Nikethamide is relatively without toxicity It must be given in large amounts intravenously to be effective. It is not effective for restoration of muscle tonus when administered by mouth or intramuscularly.

Transmission of Kala-Azar in India: Case Against Sandfly. R. H. Malone and A. G. Brooks.—p. 484.

Early Diagnosis of Kala-Azar.—According to Lowe, present conditions in eastern India favor an epidemic of kala-azar. In the past, diagnosis was usually delayed until the third or fourth month of fever. Earlier diagnosis was often impossible because spleen puncture is advisable only when the spleen is considerably enlarged, and moreover the aldehyde and antimony tests become positive only after this period. Patients who developed kala-azar frequently suffered from recurring bouts of fever which were either untreated or treated as due to malaria or some other condition. The author presents reports of patients with kala-azar who have been seen early in the disease. The most constant finding in the early cases has been the irregular temperature of remittent nature with a relatively rapid pulse rate and the absence of severe toxemia. In the early diagnosis of kala-azar the general clinical picture and the nature of the fever are the most important considerations; sternal puncture with staining for Leishmania donovani provides the most reliable method of confirmation. The complement fixation test done with the Witebsky, Klingenstein and Kuhn antigen or some modification of it is the next most useful confirmatory measure. With clinical observations and the use of these tests, diagnosis should usually be possible within three weeks of onset.

Complement Fixation Test in Kala-Azar.—Sen Gupta reports from the Calcutta School of Tropical Medicine 920 cases in which the complement fixation test was done according to the technic described by Greval, Sen Gupta and Napier with an antigen prepared according to the Witebsky, Klingenstein and Kuhn method from Kedrowsky's bacillus. A positive reaction was obtained in 93 per cent, a doubtful reaction in 6 per cent and a negative reaction in 1 per cent of all cases of kala-azar. In 99 per cent of all cases likely to be considered in the differential diagnosis of kala-azar a negative reaction is obtained. In 1 per cent a doubtful reaction may be obtained. A positive reaction is obtained in a few cases of chronic pulmonary tuberculosis, but such cases are readily excluded by their clinical features. The antigen prepared from Kedrowsky's bacillus is somewhat inferior. It is probable that with the antigen prepared locally from the human tubercle bacillus better results will be obtained. This test provides a method of laboratory diagnosis at a stage when all other procedures except a sternal puncture are negative. In several cases the positive reaction was obtained within three weeks of onset. Specific treatment of kala-azar causes the reaction to become negative or produces a lowering of the degree of complement fixation.

Blood Levels of Sulfapyridine in Pneumonia.—Dick previously called attention to the fact that in Glasgow type II pneumococcus infections carried a fatality rate of about 14 per cent when only a sulfonamide drug was administered and that the addition of an autogenous vaccine failed to improve the results. A more intensive course of chemotherapy was suggested. Results of therapy in 161 patients with pneumonia as judged by the duration of primary pyrexia, the incidence of complications and the final outcome of the disease could not be correlated with the blood concentration of the drug. A more intensive course of chemotherapy in pneumonia does not appear to be justified, and there appears to be no reason for exceeding the recognized dosage of 2 Gm. initially followed by 1 Gm. every four hours.

Hemothorax.—In most hemothoraces the blood remains liquid. It is now generally recognized that clotting occurs, but the hematoma is rapidly defibrinated so that the actual gel form of clot is transposed into shreds of fibrin floating in a pool of liquid blood. To get some evidence on the behavior of intrapleural blood, investigations have been made on a number of hemothoraces. No instances of infected hemothorax has been included, since inflammation would alter the pleural reaction. Only those cases have been included in which the first two aspirations yielded at least 2 pints. The blood may reach a volume of several pints and in the free pleural sac this clots normally but is rapidly defibrinated. A liquid mass is formed in which fibrin shreds may be deposited. Fairly quickly a serous effusion develops, and it is this effusion that accounts for the main deposit of fibrin that complicates the later picture. The sooner the original hemothorax can be evacuated the better will be the chances of functional recovery. Clotted hemothorax is relatively rare, but coagulation of an effusion of high fibrinogen content gives rise to the clotted fibrothorax. In the presence of a clot—blood or fibrin—active surgery may be required. A small thoracotomy allows the cavity to be cleaned and in selected cases permits removal of the restricting layer of fibrous tissue over the lung. Breathing exercises are of great value in reestablishing full expansion of the collapsed lung.

Gastrectomy and Skeletal Decalcification.—Bonorino Udaondo and Castex report clinical, radiologic and chemical investigations on 41 patients who had undergone gastrectomy for gastric or duodenal ulcer or for gastric carcinoma or sarcoma. The time that had elapsed between the gastrectomy and the radiologic study and the investigation of the mineral metabolism varied between four months and twenty-one years, but in the majority three or more years had elapsed. The authors found that the incidence of osseous decalcification in the lumbosacral and pelvic bones (the only bones studied by them) was extremely frequent, and they believe that the digestive and nutritive status produced by the gastrectomy is the primary factor. The investigations revealed that there are other contributing factors in the causation of this osteomalacia, such as too little exposure to sunlight with deficient synthesis of vitamin D and insufficient ingestion of calcium in assimilable form due to inadequate alimentation and digestive disturbances. Cancer, advanced age and endocrine disorders are factors that create or intensify decalcification. Account should be taken of this combination of causes of osteomalacia in patients subjected to gastrectomy and recourse should be taken to measures that nullify the deleterious action of these factors, because preventive measures are usually more effective than is treatment of the established process.

Ligneous Thyroiditis.—Strada and his collaborators mention thyroid cirrhosis, petrous thyroiditis and several other terms for the condition which was first described by Riedel in 1896. They describe 2 cases of ligneous thyroiditis, 1 in a boy aged 15 and 1 in a woman aged 44. The diagnosis is based on three main symptoms: hardness, invasion of neighboring tissues and compression. Two other disorders cause considerable induration of the thyroid, namely cancer and Hashimoto's disease (struma lymphomatosa). Cancer can be differentiated by the grossly nodular surface and early metastases in the lymph nodes of the neck. In Hashimoto's disease, which some regard as the primary stage of ligneous thyroiditis, there exists a uniform enlargement of the entire gland, but the surface is smooth and slightly lobulated; there is no adherence to the neighboring organs; and it occurs almost exclusively in women of menopausal age. The treatment of ligneous thyroiditis consists in subtotal thyroidectomy in order to overcome the compression. It produces favorable results even if only a small part of the tumor is extirpated. In both of the reported cases the operation was well tolerated and great relief obtained.

*Immunization Against Scarlet Fever in Camps of Hitler Youth. J. Wolff. —p. 727.

Five Day Cure of Malaria.—Hauer reports results of intensive treatment of 566 cases of tertian, quartan and tropical malaria during the period from December 1942 to June 1943. A five day course was practiced. One tablet of 0.01 Gm. of plasmochin three times daily and two tablets of 0.1 Gm. of atabrine three times daily were given for the first three days. One tablet of 0.1 Gm. of atabrine three times daily was given on the fourth and on the fifth day. Hydrochloric acid was administered at the same time. Tolerance was convincingly good. The effects of the drugs as parasiticides and as antipyretics were at least the same as if not better than those of a ten or twelve day course which had been employed previously. The early effect of the plasmochin on the gametes may support the control of the mosquito borne infections in the endemic regions of tropical malaria. It is too early for a definite statement with regard to relapses, but it seems likely that the results of the five day course were not less favorable than those of the other methods. A large scale trial is recommended.

Intrasternal Infusions.—Intrasternal transfusions represent a satisfactory substitute in cases in which the intravenous route is not available. The intramedullary route is suggested for cases in which the veins of the extremities are obliterated or are too small. Intrasternal infusions are of the greatest value in wartime for emergency blood transfusions in cases of severe injuries complicated by collapse or shock. Because the needle remains fixed in the cortical substance, the sternal infusion method is indicated in motor unrest of various origin, such as that of diabetic coma, acute circulatory collapse, malignant diphtheria and drug poisoning. The intramedullary route is particularly suited for infants and young children. Henning opposes Tocantins' opinion that the femur or the tibia should be used instead of the sternum in children under 3 years of age. By inserting the needle at an angle, intrasternal injections and infusions may be used in infants. The intramedullary injection into any bone is to be considered in case of failure of the intrasternal injection. This failure may be caused by clotting of the bone marrow and may be prevented by flushing the cannula with a 3.8 per cent sodium citrate solution prior to puncture.

Immunization Against Scarlet Fever.—Children from various parts of Germany were brought to Lower Silesia, where the incidence of scarlet fever was high. Concentration of the children in camps where they had to live permanently, sharing meals and bedrooms, increased the risk of direct infection. Prophylactic active immunization was carried out with "Scarlet Fever Adsorption Vaccine K, Behring," a suspension of killed hemolytic streptococci in an attenuated toxin solution which had been adsorbed with aluminum hydroxide. The vaccine contained an antitoxic component in addition to the antibacterial component. Preliminary immunization experiments were carried out on 40 children whose Dick reaction was positive, 0.5 cc. of the new vaccine being given twice every two weeks. Dick tests were then repeated with negative result in all the children. There were no untoward reactions, such as fever or eruption, except for mild local reactions such as redness or swelling. The same good results were obtained from immunization of 58 children to whom 0.5 cc. of the vaccine was given three times at intervals of four weeks, and from the immunization of 400 children to whom 0.5 cc. of the vaccine was applied twice at an interval of two weeks. Mass immunization with two applications of the vaccine to the upper arm at a four weeks interval was carried out on 3,400 young people from 6 to 16 years of age. Diphtheria vaccine was given at the same time in the other arm. Not a single case of scarlet fever occurred in the camps. In some of the camps, with children between the ages of 10 and 14 years the immunization was performed with "Scarlatox-Asid-Vaccine" instead of the scarlet fever-adsorption vaccine K, Behring. The difference between the two vaccines consisted in the purification method used for the toxin. Three applications at intervals of two weeks were made. Twenty-two children had temperatures up to 103 F. Headache and pharyngitis were present and an eruption occurred in 8 instances. The local conditions in the camp were believed to be responsible for these untoward reactions.

Book Notices

Endocrinology of Woman. By E. C. Hamblen, B.S., M.D., F.A.C.S., Clinical Professor of Endocrinology and Associate Professor of Obstetrics and Gynecology, Duke University School of Medicine, Durham, North Carolina. Cloth. Price, $8. Pp. 571, with 157 illustrations. Springfield, Illinois: Charles C Thomas, 1945.

The author's decision, as stated in his preface, to prepare an essentially new book rather than to refurbish his former volume on Endocrine Gynecology, published in 1939, was a wise one. The present work is undoubtedly a great improvement over the earlier one, which contained much good material, but the arrangement was poor and it was difficult for the reader to find what he might be looking for. In the present streamlined volume, to use the author's own adjective, the subject matter is presented in a systematic and orderly fashion, under five chief subdivisions.

The first of these presents a short but adequate discussion of the history, embryology, anomalies, anatomy, physiology, chemistry and interrelations of the various endocrine glands. The second is devoted to applied endocrine physiology, including a discussion of the endocrines in the fetus and newborn, childhood and adolescence, together with a very satisfactory review of the endocrinology of menstruation and the climacteric. While this section incorporates a good deal of material from the author's previous volume, it has been brought up to date and attractively rearranged.

The third section, dealing with endocrine diagnostic methods, is one of the most valuable in the book. Not only does it describe the innumerable laboratory tests so often necessary in the diagnosis of endocrine problems but it also discusses such clinicolaboratory procedures as endometrial biopsy and vaginal smear study. Hamblen expresses skepticism as to the clinical value of vaginal smear studies, and in this skepticism we heartily concur.

The fourth part of the book deals with functional disorders of the endocrine glands, including many not closely related to the gynecologic field. There can be no criticism of this broad scope, since the gynecologic endocrinologist soon learns that he cannot interpret his problems intelligently if he tries to fence himself within pelvic limits.

The last section of the book deals with endocrinology applied to gynecologic disease and naturally includes the author's views as to the therapy of functional disorders. Curiously enough there is no mention of the treatment of amenorrhea, one of the most troublesome of gynecologic problems. The only plan of treatment of functional bleeding discussed is the author's method of "cyclic regulation" and "pituitary regulation." The plan of beating a dysfunctioning and probably refractory pituitary into cyclic submission by ovarian therapy sounds pretty, but, aside from the duration, expense, inconvenience and general ponderousness of the regimen it has not given as good results in the hands of others as appear to have been obtained by Hamblen. Throughout the book, and even in its preface, the author expresses undying opposition to androgenic therapy under any circumstances, and this extreme view seems unreasoning. He states that such treatment is always "unphysiologic," but so is the accepted diethylstilbestrol treatment of prostatic carcinoma, to mention only one of many possible examples. Every sensible gynecologist recognizes the limitations of androgen therapy as well as its hazards if employed indiscriminately, but many find a limited indication for its employment in this present makeshift era of organotherapy.

The chapter on dysmenorrhea is poor. Hamblen is evidently still a believer in the so-called nasal treatment of dysmenorrhea by cautery of Fliess's spots with trichloroacetic acid crystals, a curious anachronism in an otherwise modern textbook. It is impossible for any one in the present confused era of organotherapy to write a book which would meet the approval of all other endocrinologists, and many will question some of the therapeutic advice given by Hamblen, such as that of giving estrogens cyclically or according to a rather fixed schedule in the treatment of menopausal symptoms. The therapeutic section of this book will be definitely less valuable to its readers than those portions dealing with physiology and diagnosis.

The illustrations are numerous and well chosen, especially the photomicrographs illustrating all manner of endometrial patterns. The publishers have done a good job with typography and format. The book as a whole is one which can be warmly recommended as a very worthy addition to the ever increasing number of works devoted to this expanding field.

Pastoral Work and Personal Counseling. By Russell L. Dicks. Cloth. Price, $2. Pp. 230. New York: Macmillan Company, 1944.

This work by the chaplain of Wesley Memorial Hospital is written for the "average clergyman." The author has had considerable experience in dealing with illness and is co-author with Dr. Richard Cabot of "The Art of Ministering to the Sick." For this reason the book is of interest to the physician. The author stresses the lack of preparation of many clergymen for counseling with persons in conflict and feels that the physician and social worker have almost shouldered the clergyman out of his own field. The book deals with methods in approaching individual problems and correctly emphasizes the importance and nature of the relationship of the pastor to members of his church as counselor. By example and by records of interviews the author attempts to place before the reader his own basic attitudes and his actual experience. This is a candid, refreshing work, well suited to its purpose. Its scope is distinctly limited, since there is no pretense of presenting principles underlying the disturbing behavior or disturbed feelings of those whom the pastor attempts to aid. The present day theological student would wish more thoroughgoing ground work in psychology and psychiatry. The author is quite direct in delimiting problems to which the pastor should address himself and stresses the appropriate working relationship between pastor, social worker and physician. This is an honestly written book that evidences the warmth and human understanding of the author.

The Principles and Practice of Tropical Medicine. [Part I.] By L. Everard Napier, C.I.E., F.R.C.P., Director and Professor of Tropical Medicine, Calcutta School of Tropical Medicine. Cloth. Price, 25 rupees. Pp. 522, with illustrations. Calcutta: Thacker, Spink & Co. (1933), Ltd.; London: W. Thacker & Co., 1943.

Part I of a two volume work, the second of which is yet to appear, considers measures for mitigating the effects of tropical climate, diseases due to the direct effects of tropical climate, malaria, leishmaniasis, trypanosomiasis, the relapsing fevers, rat bite fever, the typhus fevers, Oroya fever, yellow fever, Rift Valley fever, the dengue sandfly fever group, plague, tularemia, the undulant fevers, melioidosis, the intestinal fluxes and leprosy. The work is admittedly an introductory textbook on tropical medicine and because of several excellent clinical descriptions and complete discussions of treatment it will be of particular value to medical students and clinicians. No attempt has been made to prepare a volume of reference for the advanced worker. Although the presentation of diseases gives major importance to the clinical side, the essentiality of proper laboratory procedures is adequately stressed. In this connection attention is called to the increased frequency with which the etiologic agents of tropical diseases may be demonstrated. The section on kala-azar reflects the author's knowledge of the disease and substantiates his rank as an authority on the subject. On the other hand, the conception that all primary infections with Endameba histolytica should be called "amebic dysentery" and all other symptoms should be considered as secondary to dysentery is at variance with most authorities on the subject. On the whole, the book is considered to be an excellent one for its purpose and should find wide use.

Etudes de psychologie médicale. Par André Ombredane, professeur de psychologie expérimentale à l'Université du Brésil, Rio de Janeiro. I. Perception et langage. II: Geste et action. Les publications savantes de l'École libre des hautes études du Brésil, 2,3. Paper. Pp. 189, with 12 illustrations; 129, with 7 illustrations. Rio de Janeiro: Atlantica Editora, 1944.

It would be difficult, if not impossible, to find in the modern literature of any country a more fundamental and exhaustive study of the problems presented here than this masterly work by André Ombredane. Only a man who commands the enormous literature of two continents dealing with aphasia, agnosia and apraxia and has the brilliance and experience of Ombredane

could give us such a critical analysis and synthetic presentation of this most difficult subject.

The author bases his chapter on aphasia on Baillarger's principle "the substitute of the involuntary verbal incitation for the voluntary one" and Hughlings Jackson's conception of diseases of the nervous system as reversed evolution, e. g. dissolution. Dissolution as a process of regression proceeds from the least organized, the most complex, the least automatic toward the most organized, the simplest and most automatic. In a uniform dissolution the highest centers are the most affected. A high (cortical) center tends to represent the whole of the organism in contrast to a low (for instance spinal) center, which represents an elementary organ capable of functioning independently of the rest of the organism. All the nerve centers are necessarily of sensory-motor constitution. There are stages of conscience corresponding to the different levels of central organization, their mental character being the more accentuated the more higher centers are engaged. Body parts predominantly employed in voluntary actions have a particularly important representation in the highest brain centers.

Under these conditions the internal evolution of the upper centers corresponds to a great multiplication of neural arrangements representing the muscles of the hands, the eyes, the speech, the retina, so much so that the dissociated or mental activity of the upper centers is in reality bound to the awakening of sensory impressions and to the concept of manual, ocular, articulate movements which mutually release themselves, get organized and develop in conformity with the symbolic values which they have acquired.

In the process of dissolution voluntary execution is found defective when automatic acts may still function normally. The question, as far as aphasia is concerned, is not which elements but which uses of speech are affected by a lesion. The author then discusses the different uses of speech. A large part of volume I, 85 pages, deals with optic agnosia and contains among others a discussion of the publication of Goldstein and Gelb. Then follows an analysis of a case of pure alexia. Two chapters on congenital dyslexia and acoustic agnosia terminate this volume.

The second volume, of 107 pages, is dedicated to the analysis of apraxia, understood as a loss of voluntary or propositional gestures. The theories of Liepman, Pick, Charles Foix and von Monakow are thoroughly discussed and at the end the relation of apraxia to aphasia is analyzed. The author finally arrives at the very concept from which he started in discussing the jacksonian concept of aphasia, e. g. that apraxia does not conform to the body anatomy but to the different conditions under which actions are performed. One should distinguish an apraxia integrated in a disturbance of the equilibrium, an apraxia as a part of a disturbed left-right and body orientation, an apraxia as part of a sensory agnosia, particularly an optic one, an apraxia as part of an aphasia and an apraxia of the type seen in dementia. Two cases of apraxia are analyzed in detail.

Handbook of Industrial Psychology. By May Smith. Cloth. Price, $5. Pp. 304. New York: Philosophical Library, Inc., 1944.

This is a useful, comprehensive book whose author has had much experience. It discusses fatigue, the environment with relation to light, temperature, noise and hours and the relationship of the individual worker to the group around him. There are also chapters on vocational guidance and selection and training and on time and motion studies. Another chapter deals with the nervous temperament and expressions of nervousness in work. Also included in the general content are discussions of accidents, grievances, misfits, sick absenteeism and labor wastage and comments on methods of investigation. In these times, so much is said and so much written concerning industrial medicine, comprehensive medical plans for workers and their dependents, hospitalization schemes and similar topics that it is most beneficial to be able to refer to a publication which deals with the basic factors influencing the reactions and conduct of industrial workers. These factors are universal and arise either out of environment or out of the reactions of one human being on another. They are commonly disregarded, often by those who talk loudest about medical care for workers, and it is to be feared that there are many who are active in the field of industrial medicine and industrial relations to whom this book would come as a revelation. This handbook is based on British experience but basically it is applicable anywhere. It is well printed, the type is large enough to make reading easy, and it is to be hoped that it will have a wide circulation among those who are engaged in an administrative capacity in personnel and medical departments in industry.

Elements of Bacterial Cytology. By Georges Knaysi, Professor of Bacteriology, Cornell University, New York. Cloth. Price, $3.50. Pp. 209, with 101 illustrations. Ithaca, New York: Comstock Publishing Company, Inc., 1944.

This is a detailed and critical treatment of bacterial structure. The author, who has an exceptional background in physical chemistry in addition to cytology, has avoided and revealed many pitfalls in a difficult subject. He has drawn on recent knowledge gained with the electron microscope. The medical bacteriologist will be disappointed, however, to find almost no use made of the great contributions of immunochemistry and the chemistry of pathogenic bacteria to the composition of the bacterial cell wall and capsule. It is regrettable too that the treponemes are described as possessing axial filaments and no flagella; recent work with the electron microscope has shown both these accepted beliefs to be in error. The specialist and graduate student in general bacteriology will find in this book critical insights into bacterial morphology and the structural basis of bacterial function and, in addition, many problems in need of critical review.

Combined Textbook of Obstetrics and Gynæcology for Students and Medical Practitioners. Revised by J. M. Munro Kerr, LL.D., M.D., F.R.F.P. & S., and others. With additional contributions by Charles McNeil, M.A., M.D., F.R.C.P., Professor in Child Life and Health, University of Edinburgh, and G. Jackson Wilson, M.B., D.P.H., Radiologist, Glasgow Royal Maternity Hospital and the Victoria Infirmary, Glasgow. Fourth edition. Cloth. Price, $12. Pp. 1,208, with 511 illustrations. Baltimore: William Wood & Company, 1944.

This edition is the fourth one which has appeared during the last twenty-one years. Like its predecessors, several of the leading British obstetricians and gynecologists are contributors. There is rarely any mention of authorship of a chapter; hence presumably each chapter was discussed by all or several of the contributors. For the first time a section on contraception is included.

In the opinion of the reviewer the following are faults in the book: In the discussion of young human ova, the Miller ovum is still regarded as the youngest despite the fact that Hertig and Rock recorded a much younger and thoroughly studied ovum; the Hertig-Rock studies were reported in 1942. Among the biologic tests of pregnancy space is devoted to such antiquated and discarded tests as Abderhalden's serum reaction, the sugar tolerance tests, the phlorhizin test, the epinephrine test, complement fixation tests and blood sedimentation tests. The authors advise against long motor or train journeys in spite of the fact that during the last few years large numbers of pregnant wives of men in the armed forces have traveled thousands of miles under the most trying conditions with practically no harm to themselves or their babies. In cases of septic abortion, emptying of the uterus is advised and, while the results are good, most American obstetricians believe that it is safer to avoid surgical intervention in infected cases of abortion. Likewise exception may be taken to the use of glycerin, pituitary extract and ergot in these cases. In the chapter on analgesia and anesthesia there is no mention of caudal anesthesia. This will astonish many of the stanch advocates of continuous caudal anesthesia and the editors of some of our popular lay magazines. The authors properly condemn the Walcher position, yet they waste an illustration on it. In the illustration demonstrating an episiotomy a lateral incision is shown, but this is the least satisfactory of all the types of episiotomy. There is a section on intrauterine douches for various purposes, but few obstetricians or gynecologists in the United States use intrauterine douches. For replacing a retroflexed uterus the authors describe and illustrate replacement with a uterine sound. This procedure carries too much risk to be recommended to general practitioners.

In spite of the foregoing criticisms, the book is full of useful information about obstetrics and gynecology. It is well written and abundantly illustrated. It will undoubtedly and deservedly continue to be one of the most popular books in England.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES, UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

STERILIZATION OF OBJECTS CONTAMINATED WITH TUBERCLE BACILLI

To the Editor:—One of the things that deserves more attention about tuberculosis sanatoriums is the matter of sterilization of the products of patients' handiwork. Information on this subject is certainly not as widespread as it should be, even in tuberculosis institutions. Tuberculosis usually spreads by inhalation of bacilli expectorated by a patient, but the possibilities of contraction by indirect contact cannot be neglected, particularly in the case of toys or other articles made by patients for the use of small children. Dry cleaning is advised to deal with woolens contaminated with tuberculous sputum, but I can find no authority stating that naphtha, gasoline or carbon tetrachloride will definitely kill tubercle bacilli. If not these agents, what part of the dry cleaning process sterilizes the cloth? As steam sterilizing or boiling ruins woolens, we must trust to dry heat in some cases. What temperature will woolen garments stand of dry heat without deterioration, and how long should woolens be subjected to a suitable dry temperature for sterilization? What are the specifications for sterilizing mattresses in a tuberculosis sanatorium? In the case of cotton or kapok filled toys covered with cotton or wool and unable to undergo wetting, what degree of dry heat should be used and for how long? Would formaldehyde vapor be injurious to wool, cotton or furs or the dye therein? How long should articles be subjected to formaldehyde vapor for sterilization? What solution is used by bottlers to sterilize bottles for carbonated beverages? Is this efficacious in destroying tubercle bacilli? Is it injurious to cloth?

B. J. Terrell, M.D., Nopeming, Minn.

ANSWER.—The department of bacteriology of a medical school subjected standard strains of Staphylococcus aureus and Eberthella typhi to Stoddard solvent for the same time that clothing is in this solvent during the cleaning process. All the organisms were killed. A pure culture of tubercle bacilli was then treated in like manner and the sediment was inoculated into guinea pigs. To date no sign of infection has developed in these animals. Other strains of tubercle bacilli are to be subjected to the same treatment, after which the final report will be published. As far as can be determined at this time, the dry cleaning process described serves to destroy tubercle bacilli.

Dry heat may be applied to ordinary woolens at a temperature of 250 F., and to carbonized woolens at 230 F. for a few minutes to one-half hour without damaging the material. Thirty minutes of dry heat to this degree is adequate to destroy tubercle bacilli. (Any heat over these temperatures tenders the cloth and drys up the dye oils and grease.)

The sterilization of mattresses by dry heat is effective. Laundering is satisfactory for cotton materials as, if color fast, they can be subjected to hot water. In the case of cotton or kapok filled toys covered with cotton or wool and unable to undergo wetting, dry heat should suffice; in fact, cotton tolerates a temperature of 400 degrees, which also is harmless to kapok.

The use of formaldehyde vapor for sterilization is falling more and more into disfavor. Rosenau states that none of the gases can be depended on to disinfect clothing, bedding or fabrics. While formaldehyde is suitable for general use, it does not accomplish more than a surface disinfection, as it ordinarily possesses small powers of penetration. Large quantities of formaldehyde vapor are lost by uniting with the organic matter of fabrics, especially woolens, which further hinders its penetration.

For a number of years the American Bottlers of Carbonated Beverages made investigations concerning the causes of spoilage. They found that by far the most important causes of biologic spoilage of beverages are yeasts. Bacteria are not so important because they are sensitive to citric acid, do not grow in sugar concentrations favorable to yeasts and are checked or entirely prevented from growing by moderate quantities of carbonic acid. The molds rarely cause spoilage. Much investigation led the American Bottlers of Carbonated Beverages to the recommendation that unclean bottles be exposed to a 3 per cent alkali solution, of which not less than 60 per cent is caustic (sodium hydroxide) for a period of not less than five minutes at a temperature of not less than 130 F. or an equivalent cleansing and sterilizing process. While this is probably adequate to destroy tubercle bacilli, an extra five or ten minutes is suggested to insure safety. In one large bottling plant a commercial powder, consisting of sodium hydroxide and trisodium phosphate, is used in a 3.5 per cent solution. The bottles are kept in this for fifteen minutes, with a temperature ranging from 130 to 150 F. This procedure should be entirely adequate to destroy tubercle bacilli. In the state where this concern operates there is a requirement that washed bottles contain less than 100 bacteria per bottle. However, numerous tests of washed bottles by the aforementioned method have shown an average of only 6 or 7 bacteria per bottle, none of which were pathogens except Staphylococcus aureus. These probably reached the washed bottles through the air. There is no report available of tubercle bacilli having been recovered from washed bottles.

EXCRETION OF SULFONAMIDES AND GLOMERULONEPHRITIS

To the Editor:—What is the effect of glomerulonephritis on the excretion of the sulfonamides? What information is available on "sulfonamide block" as pertaining to the kidney?

Lloyd J. Netto, M.D., West Palm Beach, Fla.

ANSWER.—The question is rather ambiguous. If a glomerulonephritis already exists, it can be anticipated that excretion of the sulfonamides will definitely be inhibited and blood levels of these compounds will be maintained at a greater height than if there was no renal involvement. On the other hand, if the only consideration is that glomerulonephritis might result from the use of the sulfonamides it should be pointed out that sulfanilamide has been used successfully in the treatment of acute hemorrhagic (glomerular) nephritis. Sulfapyridine and sulfathiazole, and probably sulfadiazine, should not be employed in the treatment of an infection with an accompanying nephritis. Sulfapyridine and sulfathiazole may injure the kidneys either through intrarenal precipitation of crystals or by a direct action on the kidney cells. Sulfadiazine produces kidney damage only to a limited extent. Under any circumstance, until more definite information has been obtained, if sulfadiazine is used when glomerulonephritis is already present it should be accompanied by sufficient sodium bicarbonate to keep the urine alkaline.

An excellent account of the renal complications following sulfathiazole therapy by Winsor and Burch appeared in THE JOURNAL, April 18, 1942, page 1346. A more recent article is that of Vilter and Blankenhorn in THE JOURNAL, Nov. 11, 1944, page 691.

Even in the presence of a glomerulonephritis, were the indications sufficiently pronounced to warrant the use of sulfadiazine this sulfonamide salt should be given with the reasonable certainty that crystalluria will not develop if adequate sodium bicarbonate and fluids sufficient to bring about a daily output of 1,500 cc. are given.

SULFONAMIDES NOT USEFUL IN POLIOMYELITIS

To the Editor:—Is there any evidence that the sulfonamide compounds have a detrimental effect in acute anterior poliomyelitis? Is the rapidity of the extension of paralysis or the extent thereof affected by these drugs?

M.D., Puerto Rico.

ANSWER.—Extensive work has been done on the effect of sulfonamide therapy on experimental poliomyelitis in mice (Kramer, S. D.; Geer, H. A., and Szobel, D. A.: The Chemoprophylactic and Therapeutic Action of a Wide Variety of Chemical Compounds on Two Neurotropic Virus Infections in Mice, *J. Immunol.* **49**:273 [Nov.] 1944). These workers, using some forty-eight derivatives and compounds of the sulfonamide group, were unable to demonstrate any ameliorating effects on the course of the disease. These workers do not mention any definite deleterious effects in the animals subjected to this type of therapy.

STERILIZATION OF LOCAL ANESTHETICS FOR USE IN EYE

To the Editor:—Please give me information on sterilization of eyedrops for local anesthesia to be used in cataract operations. Is there any solution in which cocaine, atropine, physostigmine or pilocarpine can be dissolved which is self sterilizing? S. F. Goldfain, M.D., Baton Rouge, La.

ANSWER.—Eyedrops are best sterilized by heat. The dropper and the container must also be sterilized. The dropper and a small flask containing the solution may be placed in a small glass jar, such as is used for preserving fruits; this should be autoclaved ten minutes under 20 pounds of steam. In the solution it is well to incorporate a bacteriostatic agent aimed to keep the solution sterile. The universal bacteriostat (an antiseptic as distinguished from a germicide) for solutions of alkaloids is chlorobutanol in a strength of 1 to 0.5 per cent. The chlorobutanol should not be relied on to sterilize a solution as is shown by the following experiment: One drop of a culture of Staphylococcus aureus was dropped into a bottle of water saturated with chlorobutanol. After one, two and three hours samples were tested and there was copious growth, showing that the chlorobutanol did not kill the staphylococci. Another method of sterilizing the solution is to boil the water and while it is boiling add the alkaloid, which can be obtained in tablet form for easy measurement, after which it need not boil more than half a minute.

Precautions: Some of the alkaloids, especially cocaine, are decomposed by heat. If the solution is carefully kept acid p_H 4.5 (which is the p_H when cocaine is dissolved in distilled water without any addition), very little decomposition will take place, but if the solution is even slightly alkaline the cocaine will be rapidly decomposed. It is not safe to use chlorobutanol to sterilize the solution, and if other more powerful antiseptics are used, to be effective they must be in such strength that they will be decidedly injurious to the epithelium of the eye. These include zephiran, which should not be stronger than 1:3,000, and metaphen, which is marketed in the strength 1:2,500 to be diluted with equal parts of water to make 1:5,000. Metaphen comes buffered to a p_H of 7 plus and is therefore much too alkaline for use with cocaine. The cocaine solution should not be reheated over and over because it will become decomposed. Therefore only small quantities should be prepared at one time.

ROCK WOOL NOT CAUSE OF PNEUMONOCONIOSIS

To the Editor:—In the more recent installation of refrigeration in numerous war plants, I have observed in several patients a condition apparently caused by inhalation of rock wool and other fine particles passing into the lung proper. Please give the diagnosis, prognosis and treatment of such a condition. W. A. Newton, M.D., Beaumont, Texas.

ANSWER.—Information on the chronic pathologic effects of inhaled rock wool is practically nonexistent. Fibers of glass wool are not inhalable, and it is assumed that rock wool is likewise excluded from the lungs because of the size and physical properties of the fiber. X-ray films of persons exposed to this material tend to confirm the inference, for none of those observed in any way resemble the reaction to the known fibrous dust asbestos. If there is any change noted at all it is limited to an exaggeration of the normal linear markings due to particles and broken fragments of the fiber; such changes are rarely associated with symptoms or disability. Diagnosis would depend on a history of exposure over periods measured in years, the demonstration of a uniformly altered x-ray pattern in a considerable group of workmen and a physical examination for evidence of disability. The prognosis should be good, and no disability or increased susceptibility to pulmonary infection is likely. Treatment is entirely prophylactic.

BAR'S SYNDROME, OR COLIBACILLOSE GRAVIDIQUE

To the Editor:—I have a patient on whom a diagnosis of Bar's syndrome, or colibacillose gravidique has been made. De Lee's textbook seems to be the only one that mentions it. The *Quarterly Cumulative Index Medicus*, starting in 1920, lists references only to foreign journals. The patient is a primipara in her ninth lunar month who has had spiking fever, pyelitis and jaundice since July 1944. She had appendicitis in July. What information is available on this disease, especially as to prognosis and treatment? W. J. Schecter, M.D., Indianapolis.

ANSWER.—In De Lee-Greenhill's "Principles and Practice of Obstetrics" (ed. 8, Philadelphia, W. B. Saunders Company, 1943, p. 509) appears the statement:

"Bar has called attention to a syndrome of pain in the region of the gallbladder, the ureters and the appendix, with occasional fever, the pathologic basis being a cholecystitis, ureteritis and appendicitis. He calls it 'colibacillose gravidique.' This is a not rare condition in pregnancy. Bacteriuria accompanies it *(Vignes)*."

The Vignes reference is to a book, but while the Bar syndrome is mentioned in the book the original Bar reference is not given. Likewise, in a book entitled "Pratique obstétricale" (Paris, Masson et Cie., 1935, p. 11) L. Devraigne speaks of the Bar syndrome and, instead of giving the original Bar reference, quotes Tarnier and Vignal and Budin as his sources. Devraigne says that because of the constipation which is common in pregnancy the colon bacilli can gain access to the blood and produce a bacillemia. The latter has three sites of predilection, the gallbladder, the appendix and the renal pelvis. In the puerperium the Bar syndrome may simulate puerperal infection. P. Desgeorges (*Rev. gynéc. et obst.* **34**:335, 1936) speaks of a colibacillemia due to infection of the lymphatic system by the colon bacilli from the intestine.

As is evident from the foregoing quotations, the French obstetricians have been strongly impressed with the idea that colon bacilli can invade the blood or lymph stream and produce trouble. A search of the *Quarterly Cumulative Index* as far back as 1916 failed to reveal Bar's original paper, if there was one. Likewise no cross reference to it could be found.

Devraigne recommended disinfection of the intestinal and urinary tracts with cultures of lactic acid because, he said, these cultures create a pathogenic medium for colon bacilli. He also suggested the use of collargol, autovaccines, serum, bacteriophage, methenamine and a vegetable diet. Today it is recognized that most of this therapy is not only useless but also unnecessary. The sulfonamides, especially sulfathiazole, offer the most promising line of treatment.

LIGATION OF EXTERNAL CAROTID FOR INTRACTABLE EPISTAXIS

To the Editor:—In 1940 I did a ligation of the right external carotid artery to control an intractable unilateral right epistaxis. This procedure was decided on only after all other measures had failed; anterior and posterior tamponade, local and general styptics, cauterization, blood transfusions and, in an endeavor to visualize the bleeding vessel, a submucous resection had all been tried. The patient, a man aged 67, hypertensive with pronounced sclerosis, continued to bleed until almost exsanguinated. Ligation of the right external carotid artery was done under local anesthesia, and the epistaxis was immediately and permanently controlled. During the past month the patient has had several slight hemorrhages from the left nostril. Naturally he is apprehensive after his unpleasant experience and is even now anticipating a ligation of the other external carotid. Would there be any contraindication to such a procedure should the necessity present itself? M.D., Ohio.

ANSWER.—There should be no contraindication to ligation of the left external carotid artery if this procedure becomes necessary. In performing the ligation it might be well to consider placing the ligature above the facial artery branch to insure adequate circulation to the structures below the facial artery supply.

ENCEPHALITIS

To the Editor:—A woman aged about 60 has virus encephalitis. Examination of the spinal fluid showed on Aug. 7, 1944 globulin 2 plus, 17 white blood cells, 92 per cent lymphocytes, total protein 117, colloidal gold test negative, on August 21 globulin 1 plus, 23 white blood cells, 75 per cent lymphocytes, total protein 186, colloidal gold 0001232100, on September 15 globulin slightly positive, 18 white blood cells and sugar 50 mg. per hundred cubic centimeters. What is the latest treatment for this? Fred R. Isaacs, M.D., Lawrence, Kan.

ANSWER.—The diagnosis of virus encephalitis seems doubtful in this case in view of the relatively low cell count and protein and the apparently sporadic incidence. The spinal fluid picture is compatible also with brain abscess or infarction.

There is not any generally accepted treatment for such cases. If the patient suffers from a sporadic encephalitis or encephalopathy of the white matter of the brain there is a fair outlook for spontaneous improvement. If the disease has attacked the spinal cord and the bladder is involved, tidal irrigation should be instituted. Foci of infection should be sought and eradicated.

SIGNIFICANCE OF NYSTAGMUS WITH CALORIC TEST

To the Editor:—A patient gave no response to the caloric vestibular test and a diminished response by the Bárány rotating test. Could such reactions ever be considered hysterical in nature? This patient had certain manifestations of hysteria, but he also had meningovascular syphilis. Could lack of response to the caloric vestibular test be produced by hysteria? Major, M. C., A. U. S.

ANSWER.—As the nystagmus occurring with a positive caloric test is the result of impulses through nerve pathways in the brain stem independent of the cerbral cortex, a true hysteria would not be expected to have any influence on the caloric vestibular reaction. Hysterical deafness does occur as the result of suppression of consciousness of the impulses which reach the cerebral cortex.

FEMALE INFERTILITY

OUR DIAGNOSTIC RESPONSIBILITIES

GEORGE H. GARDNER, M.D.

CHICAGO

It is amazing that women tend to accept full responsibility for their failure to conceive, and it is equally inconsistent that communications on this problem are usually entitled "female sterility." The term female sterility implies that husbands are usually fertile, whereas in my own experience more than half of the husbands must either share or accept full responsibility for a childless union. A man cannot be absolved from responsibility for his wife's failure to become pregnant simply because his semen contains some actively motile spermatozoa; we must be more critical than that in our evaluation of seminal fluid.

To call these women sterility problems is inappropriate for other reasons. There are few individuals, either men or women, who can be considered absolutely fertile and, conversely, very few who are absolutely sterile. Human beings, at best, are only relatively fertile. Furthermore, there must be varying degrees of relative fertility even though there is no scale by which such relative fertility can be measured; e. g., many couples of whom both the husband and the wife must be of high fertility have no difficulty in achieving pregnancies as promptly and as frequently as they wish; other couples of whom one spouse is apparently normally fertile and the other only moderately fertile have children—but it may be months before the wife becomes pregnant. On the other hand, the marriage of individuals who are both of low fertility is likely to result in no progeny. Occasionally such unions are terminated; subsequently each spouse remarries and both achieve pregnancies by the second marriage, possibly because each new spouse is an individual of high fertility.

Furthermore, the majority of childless marriages do not result from an absolute sterility either in the husband or in the wife: they are instances of relative infertility brought about by a multiplicity of factors in both spouses; some of these factors may seem trivial but, added together, they are sufficient to prevent conception. Success in the relief of barrenness therefore depends on thorough examination of both the husband and the wife followed by systematic elimination of every possible contributing cause from each of them.

From the Department of Obstetrics and Gynecology, Northwestern University Medical School, and the Gynecologic Service of Passavant Memorial Hospital.

Read before the joint meeting of the Section on Obstetrics and Gynecology and the Section on Urology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 16, 1944.

The physician whom the wife consults is obligated to make a diagnosis, i. e. to discover all factors which may contribute to her infertility. He must not jump at conclusions and he dare not take anything for granted. His examination must be thorough, and as a minimum it should include (1) a complete general physical survey, (2) a search for gross abnormalities in the female generative tract, (3) an evaluation of the male factor, (4) study of the uterine cervix, (5) testing of the oviducts for patency and (6) an investigation of the endocrine system.

At her first visit the wife is subjected to a general physical examination. At this time one should also attempt to evaluate the function of the glands of internal secretion from her height, weight and body configuration, together with the distribution of fat and hair.

The lower genital tract is searched for infection—leukorrheal discharges, especially those resulting from cervicitis, are important. Not only is the cervix inspected but its canal is tested with cervical dilators to determine whether it is adequately patent.

The size of the uterus has some significance. Hypoplasia of the uterus may be suspected either from the presence of an elongated small cervix with tiny external os or from the difficulty experienced in palpating the corpus; the length of the uterine cavity is easily ascertained with a sound. Long ago I learned that some young women with moderate hypoplasia of the uterus became pregnant with amazing alacrity.

Retrodisplacement of the uterus, with anterior tipping of the cervix away from the seminal pool, has probably been overemphasized as a cause of infertility. Following Sampson's description of endometriosis, retroflexion assumed a more important role in this problem. Pelvic endometriosis may follow retrograde menstruation through the oviducts, and such backflow of menstrual blood is most likely to occur when the cervix is stenotic, the uterus is retroflexed or fibroid tumors distort the uterine cavity. Pelvic endometriosis is found frequently in a private clientele, especially among young women who fail to become pregnant. Thus far there is no convincing explanation for the low fertility of women with pelvic endometriosis; their oviducts are patent; they ovulate, and they may become pregnant—but not frequently. This condition should be suspected when the uterus is retroflexed and fixed, the ovaries are enlarged and adherent, and when there are tiny, firm, sensitive nodulations either in the cul-de-sac, in the rectovaginal septum or on the uterosacral ligaments. If the patient complains of dysmenorrhea that has been acquired during adult life and consists, in part, of pain referred to the rectum, one can be almost certain that one is dealing with pelvic endometriosis. In my experience endometriosis is a most frequent cause of infertility.

Gynecologists disagree about the relationship of uterine fibroids to a woman's failure to conceive; I doubt that they are often responsible for infertility.

Masses in the region of the oviducts and ovaries may be either residues of pelvic inflammatory disease or cystic ovaries, signifying either previous inflammation, endometriosis, endocrine imbalance or new growths. All are of importance in the problem of relative fertility.

The next step, not the last, is an examination of the husband's semen. Preferably, the specimen should be obtained after several days of continence. The semen is collected and transported in a clean glass container, not in a rubber condom, which tends to inhibit the motility of spermatozoa. The semen should be kept at room temperature, since spermatozoa die more quickly at body temperature. 1. One should determine the amount of semen (it should be about 4 cc.); most of our specimens are obtained by coitus interruptus, frequently some of the specimen is lost and I doubt that the volume of a specimen is of great import. 2. The number of spermatozoa per cubic centimeter is vital (the normal is about 100 million per cubic centimeter); every specimen of semen must have a sperm count. 3. Eighty-five per cent of the spermatozoa should be actively motile and migrating at room temperature for hours after ejaculation. 4. One should also search for adventitious elements, such as leukocytes and red blood cells. 5. The morphology of the spermatozoa is studied in stained smears (at least 80 per cent should be normally formed).

Most husbands consider themselves fertile if they are sexually potent; they actually believe that "patent oviducts plus a potent male" should invariably result in a pregnancy. Too often physicians are guilty of further pampering this masculine ego by accepting, as normal, any specimen of semen which contains some actively motile spermatozoa. The following observation by Mazer and Israel [1] is extremely pertinent: "The degree of fertility of the male decreases, and approaches zero, with diminution in the volume of semen, decline in the number and viability of spermatozoa, and with an increase in the percentage of abnormal forms." Consequently the accepted criteria for a normal specimen of semen are reiterated: amount, 3 to 4 cc.; number of spermatozoa, approximately 100,000,000 per cubic centimeter; motility, 85 per cent actively motile and migrating at room temperature; morphology, 80 per cent normally formed; and, finally, there should be no more than an occasional leukocyte or red blood cell per high power field. Husbands must be referred to a urologist if their semen does not conform in all respects to the aforementioned criteria. Although only one spermatozoon is required to fertilize an egg, the husband with a reduced sperm count is essentially sterile.[2]

Failure to recognize deficiencies in semen has been responsible for many failures in the management of barren marriages. Possibly it would be best if all husbands were examined by a urologist, but it must be by one who is especially interested in the problem of male infertility.

Patency of the oviducts is determined by transuterine insufflation with carbon dioxide gas. I prefer an apparatus which receives carbon dioxide at a constant pressure, measures the volume of gas which passes into the abdomen and includes a mercury manometer. The ideal time to make this test is three to seven days after the conclusion of a menstrual period. Under normal conditions, gas flows through the oviducts freely at a pressure that fluctuates between 40 and 80 mm. mercury. If gas fails to pass through at 180 to 200 mm of mercury the pressure should not be carried high for fear of traumatizing the oviducts. The position of the cannula in the uterus is changed several times, and gas pressure each time allowed to rise to 180 mm., before it is assumed that gas is not going to pass through the oviducts at that test. Insufflation tests should be repeated three or four times, preferably at monthly intervals, before one is justified in concluding that the oviducts are actually blocked. Intrauterine injection of a radiopaque substance is seldom indicated; this procedure is reserved for patients who wish to consider surgical relief from occluded oviducts. The chief value of hysterosalpingography is to demonstrate the exact site of tubal obstructions. Lipiodol and similar oily opaque mediums are not innocuous; sometimes they cause tubal inflammation and, if retained in the oviducts, they may initiate a foreign body reaction.

The next examination is a Huhner test. This should be performed at the time of ovulation, i. e. twelve to fourteen days before the expected onset of a menstrual period. The wife reports for examination several hours after coitus. One should still find spermatozoa in the vaginal vault, but they will probably be immotile because spermatozoa are killed rather quickly by normal acid vaginal secretions. In normal persons the clear glairy endocervical mucus, aspirated with a Luer syringe two to four hours after intercourse, should contain 3 to 15 actively motile spermatozoa per high power field.

Consequently, the Huhner test demonstrates (1) whether intercourse has been consummated normally, (2) the ability of spermatozoa to ascend into the cervical canal and (3) the effect of endocervical secretions on the spermatozoa. Dead spermatozoa in the cervical canal are indicative of endocervical hostility; this usually results from an endocervicitis where there is a mucopurulent discharge. Eradicating an endocervicitis is one of the most direct methods of improving fertility.

After one has examined the wife's genital organs for gross abnormalities, determined the status of the husband's spermatogenesis, investigated the patency of the cervix, uterus and oviducts, checked on the delivery of semen to the cervix and the reception accorded spermatozoa by endocervical mucus, the final diagnostic step is an endocrine survey. This is the least satisfactory phase of the problem, from the standpoint both of diagnosis and of treatment.

Healthy women of childbearing age, who menstruate normally and with some degree of regularity, probably also ovulate fairly regularly. On the other hand, individuals without gross genital pathologic changes, who either menstruate infrequently, flow irregularly and scantily or bleed continuously, probably do not ovulate —such menstrual disorders usually result from disturbed function by the glands of internal secretion.

There is no direct method of proving that a woman ovulates. We are compelled to rely on presumptive evidence, namely the microscopic appearance of the endometrium at the onset of a menstrual period. Endometrial biopsies for this purpose are obtained with a suction curet, preferably within a few hours after the first show of menstrual blood. It is assumed that a woman has ovulated if her endometrium shows the normal effect of corpus luteum hormone stimulation. Such progesterone effects are hypertrophy of stroma cells, corkscrew hypertrophy of uterine glands, secretory swelling of their lining epithelial cells and good develop-

1. Mazer, D., and Israel, S. L.: Menstrual Disorders and Sterility, New York, Paul B. Hoeber, Inc., 1941.
2. Huffman, J. W.: New Factors of Clinical Significance in the Study of Human Spermatozoa, Surg., Gynec. & Obst. 73: 228, 1941.

lent of spiral arteries so that they extend into the compacta, or surface layer, of the endometrium. Although it is more difficult to interpret endometrial biopsies taken after the onset of menstrual bleeding, this is the safe time to take them. If one takes biopsies a few days before the expected onset of a menstrual period, sooner or later he will take a biopsy of a pregnant uterus.

For women who fail to ovulate, as well as for many others, additional diagnostic studies may be desirable, viz., x-ray films of the sella turcica, basal metabolic rates, blood cholesterol determinations and sugar tolerance tests.

In addition to the foregoing physical conditions, it is probable that there are psychologic factors which contribute to infertility; e. g., adoption of an infant is sometimes followed rather promptly by a pregnancy, and this despite years of previous infertility.

The diagnostic survey must be a painstaking search for every factor which might contribute to the barren marriage. The physician's next obligation is a systematic elimination of each and every contributing cause found in both the husband and his wife. We must not restrict treatment to a single major factor while neglecting the minor, more trivial causes. Due consideration to these apparently nonessential conditions may account for the success of some clinicians where others fail. However, the details of treatment do not fall within the province of this presentation.

CONCLUSIONS

1. Either the husband or the wife may be responsible for her failure to conceive; usually both are at fault and both must be examined thoroughly.

2. The diagnostic survey of such cases should be concerned with (*a*) the wife's general physical condition, (*b*) the status of her genital organs, (*c*) spermatogenesis, (*d*) delivery of semen to the cervix, (*e*) ascent of spermatozoa into the uterus, (*f*) patency of the oviducts, (*g*) ovulation and (*h*) the ability of the endometrium to receive and nourish a fertilized egg.

3. All physicians must search more carefully for deficiencies in seminal fluid; husbands should be referred to an interested urologist if the semen is not absolutely normal.

4. Most childless marriages result from a multiplicity of factors; all must be systematically eliminated.

5. One is likely to fail in the management of infertility cases unless one receives wholehearted cooperation from the husband as well as the wife; both must submit to the entire diagnostic study and both must follow through with all indicated treatment.

720 North Michigan Avenue.

ABSTRACT OF DISCUSSION

DR. ROBERT M. GRIER, Evanston, Ill.: Large and numerous uterine tumors may only indirectly cause sterility, not because conception is impossible, but because pregnancy does not carry to term, which results in a barren marriage. Endometriosis notoriously results in sterility or single child marriage. The explanation for this is as yet lacking, especially as the tubes are usually patent. Endocrine disturbances, as are evident from a careful physical examination and laboratory tests, leave us too often without procedures for therapy. Only hypothyroidism seems to offer much in the way of help. Administration of thyroid to these patients under close observation has been so repeatedly successful that its use cannot be overlooked. Why this is true is still not clearly explained. It is amazing to me how many women have been informed by physicians that pregnancy is impossible or unlikely because of retrodisplacement of the uterus. This condition in itself almost never is the sole cause of failure to conceive. When one thinks of the number of spermatozoa deposited at each male emission and their extreme motility when the male is healthy, it is hard to believe that they can fail to reach the cervical canal in sufficient numbers, even though the cervical opening is not bathed in the seminal pool. Probably 50 per cent of the women I see show absolutely no condition which could cause barrenness. Frequently the husband refuses to cooperate. It has been my plan to require examination of the husband's spermatozoa before submitting the woman to tubal patency or other tests. If the husband will not cooperate to this extent I refuse to go further, and frequently the matter is dropped after the first visit. This may be due to the man's ego or to a wife's fear of the harmful psychologic effect it will have on her husband. The fear of discovery of an old venereal infection plays its part. It also may be inconvenient because of the husband's working hours. I have found that the Huhner test is the easiest to accomplish. Even though this test is not completely accurate, certainly if abundant normal and active sperm are seen we cannot attach too much responsibility to the husband. But if this condition is not found I then ask the husband to consult an interested urologist. It appears to me that with the improvement in education of the public in these matters more and more cooperation is being attained. When the husband is pronounced normal by a urologist or the Huhner test shows him to be healthy, then the Rubin test is done. It is very gratifying to see the good results following this test. Patency may be established following some weak obstruction. This is suggested by a manometer reading which rises at first to 160 mm. of pressure and then descends to normal around 70 or 80. I am quite skeptical of the value of endocrine therapy other than thyroid medication. Its workings are still in the realm of conjecture and are not without danger.

DR. RALPH A. REIS, Chicago: It is strange that sterility has become a problem of the gynecologist. After all, 30 to 40 per cent of all barren marriages result from deficiencies of the male partner be they systemic, endocrine, developmental or inflammatory in character. Furthermore, an additional 20 to 40 per cent of barren marriages are indirectly male in origin in that the male is the donor and the female is the recipient of the infection which results in genital tract occlusion. The barren marriage always presents a double problem; that is, the necessity of investigating the fertility of both husband and wife. The intelligent layman has come to understand that an investigation of his fertility is not an investigation of his virility. Resentment or lack of cooperation is therefore gradually fading away even though such education is both slow and difficult. I should like to agree heartily with Dr. Gardner's procedure in evaluating the male partner. My difficulties in interesting urologists in male fertility studies has led me to carry out these studies myself. The site of the occlusion of the female generative tract may be the uterine tubes or the cervix. Salpingitis has always been considered the more common cause of such obstruction and is most frequently found by investigators of patients of clinic level. It has been my experience that the incidence of salpingitis in private patients is much lower than the generally accepted level. I found that 60 (48 per cent) of 125 consecutive private patients complaining of sterility had definite cervical disease. This was in contrast to the 21 (17 per cent) with evidence of salpingitis or pelvic inflammatory disease. Dr. Gardner has said that "eradicating an endocervicitis is one of the simplest methods of improving fertility." This was proved in our series and reported last year by Dr. Bernick and me; 35 of our patients were treated by cervical cautery alone. No other treatment was used for this group of patients and pregnancy followed in 27 of the 35 within twelve months. Like Dr. Gardner, I cannot produce ovulation, normal menstrual function or normal pituitary-ovarian relationships. But I am much more optimistic concerning the endocrine phase of the barren marriage than Dr. Gardner professes to be. By far the largest percentage of endocrine problems which I see are due to hypothyroidism, the one type of endocrine dysfunction which can be successfully treated. Hypothyroidism is so common in my experience that basal metabolic determinations are carried

out routinely on husband and wife as a primary diagnostic procedure. Much will be lost by considering the basal metabolic rate as a secondary or additional diagnostic study in the same category as sella turcica x-ray studies, cholesterol determinations and sugar tolerance tests. Basal metabolism rates should be determined primarily. Hypothyroid patients do respond to simple replacement therapy and one dollar's worth of thyroid substance will frequently accomplish infinitely more than one hundred dollars' worth of x-rays, biologic assays and endometrial biopsies. I feel that the majority of childless marriages are due to a single cause and that only a minority have multiple causes.

Dr. V. D. Lespinasse, Chicago: My work has been largely with the obstructive lesions in the male in relation to sterility. The commonest type of obstruction is in the lower portion of the epididymis. My contribution to this mechanical problem is in taking one definite epididymis tube and joining it to the vas. My results are about 65 to 70 per cent successful. The pelvic vas, when obstructed, needs a cross operation. That operation is a vas anastomosis and carries practically 100 per cent success, so that mechanical problems in male sterility, even after one has diagnosed them as being mechanical, still require a further diagnosis as to where that obstruction is and what the appropriate surgery is to relieve that obstruction.

Dr. Henry K. Sangree, Philadelphia: The male is at fault in about 50 per cent of nonfertile marriages. Teamwork is necessary in a study of infertility and should include an associated survey by the gynecologist, obstetrician, internist, endocrinologist and urologist. The latter by training and experience is particularly fitted to examine and treat the male partner in a barren marriage. About twenty years ago the average couple seeking relief for infertility had about a 20 per cent chance, even when they consulted physicians interested in this field, whereas today many groups of expert workers effect cures ranging from 40 to 50 per cent. Between two and nine factors are often present in the study of both partners. Dr. Meaker says that 4.7 is the average. In a consecutive study of 132 men, azoospermia was present in 12 of the first 100 cases and aspermia was present in 26. Chronic prostatitis was present in 30 cases. Endocervicitis is considered an obstructive to action by the sperm as it enters the uterus. I did 5 epididymovasostomies with 1 success. Gonococci were present in 28 per cent and, of course, many men with such infections have children. A positive serologic reaction was present in 8 per cent, even though the wife had a negative serologic reaction. A severe type of varicocele was present in 8 per cent of the cases. Penile hypospadias was present in 2 per cent. In these cases of penile hypospadias it is almost necessary for the man to wear a cover and cut a tiny hole in it, in the end, so that the spermatic fluid can come through. Hypothyroidism was present in 28. Mumps had been present in 13 cases and bilateral orchitis in 9 cases. I don't think that mumps has much to do with infertility in my study, but if a man has had bilateral inflammatory orchitis in conjunction with mumps after he has reached adulthood then I think it may be a cause. I think it is advisable to do a testicular biopsy before operation to see if there are sperm in the testes. A hundred million was the number that Dr. Gardner gave. Sixty million was the count in New York by Dr. Hotchkiss on 100 men who were perfectly normal and who had children.

Dr. A. R. Abarbanel, Washington, D. C.: The evidence at hand shows that there is a period of about twenty-four hours, ranging from twelve up to (rarely) seventy-two hours, in which sperm can penetrate cervical mucus. This fortunate event usually occurs around the tenth to fourteenth day of the menstrual cycle but has been found occasionally as early as the fifth or as late as the twentieth day of the cycle. During the remainder of the cycle the cervical mucus is not penetrable by sperm, except during menstruation. Therefore, in performing the Huhner test, one is merely going on chance. In the past few months I have seen 3 patients who were told that their tubes were absolutely closed because no gas went through at 220 mm. of mercury pressure. As a matter of fact there was present only tubal spasm. After these patients had taken oral methyltestosterone for a total dosage of 50 to 150 mg., repeat tubal insufflation revealed the carbon dioxide going through at 40 to 80 mm. of mercury pressure, while the pattern of tubal motility was normal. Two of these patients are now pregnant. The third point I would like to present is that of the management of threatened and habitual abortion. I have been able to confirm Karnaky's original contention that large doses of diethylstilbestrol will effectively maintain gestation in these patients. The therapeutic plan in the case of threatened abortion is as follows: 25 mg. of oral diethylstilbestrol at once, followed by 5 mg. every fifteen minutes until bleeding and/or cramps stop. Usually 50 to 100 mg. does the trick. Then 5 mg. three times daily is given until "life" is felt. After that 5 mg. daily until the thirty-second week of gestation. At the first sign of bleeding or cramps, 25 mg. is to be given followed by the routine outlined. In the case of habitual abortion, as soon as the diagnosis of pregnancy is confirmed the patient is placed on 5 mg. of oral diethylstilbestrol three times daily and continued until the thirty-second week. Pregnant patients tolerate these doses of diethylstilbestrol easily with no side effects. The rationale for the use of large doses of estrogen is this: Most abortions result from vascular discontinuity between the trophoblast and the maternal endometrial circulation. By maintaining vascular integrity and continuity, the estrogen maintains the pregnancy.

Dr. C. J. Stamm, Philadelphia: The excessive acid reaction of the vagina was simply mentioned and passed over. Tests recently have shown that the spermatozoa need sugar to live; therefore some one ingeniously got together a formula (glucose and isotonic solution of three chlorides), thus reducing the hyperacidity of the vaginal secretion. Whether it was the Ringer's solution or the sugar I can't say, but the addition of sugar to the douche is of real value. I strongly advise the use of this solution as a douche at night, particularly before coitus. We have heard about the inability of some women to conceive, yet with all of our present knowledge about rhythm no one today has mentioned the fact that it might not be a bad idea to instruct our patients that the proper time for them to try to conceive is at or about the time ovulation is due. In the question of the failure of the tubes to give a proper response to insufflation the previous speaker advocated the use of testosterone. I use an ordinary antispasmodic, any one will do, given to the patient for two or three days before the time when we are ready to do our insufflation. I have found repeatedly that the simple antispasmodic was sufficient to relax the musculature of the tubes and that the tubes previously reported closed were really patulous. Operations on the cervix are simple. Conization and cauterization will clear up cervicitis and endocervicitis. A word of warning—don't go too deep and do it at the proper time, which is immediately, or soon after the menstrual flow ceases, in order to prevent secondary hemorrhage, which usually occurs if it is done after the seventh day following menstruation.

Dr. J. P. Greenhill, Chicago: I should like to add something to this discussion only because of the remarks made by the last speaker concerning a douche preparation which is said to help women become pregnant. A number of physicians met to organize a new society interested in the study of infertility. This group consisted of specialists in obstetrics, gynecology, urology, physiologic chemistry and psychiatry. Among the subjects discussed was vaginal acidity and douches. It was unanimously agreed that the amount of acidity of the vagina has no bearing on fertility or infertility. Therefore douches aimed at overcoming hyperacidity or hypoacidity of the vagina or directed at prolonging the motility or life of spermatozoa in the vagina are of no value. In recent years, endometrial biopsies performed to determine the presence or absence of ovulation have revealed a relatively high incidence of unsuspected tuberculosis of the endometrium in sterile women. Since in almost every case of endometrial tuberculosis the oviducts are involved, tuberculous salpingitis is one of the causes of infertility which must be considered.

Dr. George H. Gardner, Chicago: I wish to thank all of those who have discussed my paper. They have added many interesting points which time limitations prevented me from discussing as a part of my presentation.

THIOURACIL TREATMENT OF ANGINA PECTORIS

RATIONALE AND RESULTS

WILHELM RAAB, M D

BURLINGTON, VT

Total thyroidectomy has proved an effective therapeutic procedure in the treatment of angina pectoris (Lev and Hamburger,[1] Blumgart, Levine and Berlin,[2] Levine and Eppinger,[3] Claiborne and Hurxthal,[4] Clark, Means and Sprague,[5] Scherf,[6] Singer[7] and others).

Eppinger and Levine[8] expressed the belief that the complete removal of the thyroid gland alters the response of the cardiovascular system to epinephrine and that it is the alteration of this mechanism which may, in a measure, be responsible for the relief of anginal pain Likewise Shambaugh and Cutler[9] reached the conclusion that the beneficial effect of removal of the thyroid gland in angina pectoris may be due, in a part at least, to a diminished effectiveness of the physiologic output of epinephrine Barbour and Prince[10] ascribed to epinephrine a causative role in angina pectoris as early as 1915, when they showed that it constricts the coronary arteries of monkeys and probably also of man, in contrast to those of other mammals.

Today the dominant role of adrenergic discharges in the pathogenesis of angina pectoris on effort, emotion, exposure to cold and the like appears established by numerous experimental and clinical facts

1. The specific annoxiating effect of epinephrine on the heart muscle (Barcroft and Dixon[11] Evans and Ogawa,[12] Gremels,[13] Rein,[14] Green and his associates[15]) which decidedly exceeds the oxygen requirement for the simultaneous increase of its muscular action (Gollwitzer-Meier, Kramer and Kruger[16])

2 The physiologic discharge of epinephrine into the blood stream under the very conditions which typically elicit anginal symptoms, namely exercise, emotion and exposure to cold (Cannon[17] and others).

3. The accumulation of epinephrine in the heart muscle during exercise and exposure to cold.[18]

4. The production of anginal pain through injection of epinephrine in persons with coronary sclerosis (Levine, Ernstene and Jacobson,[19] Katz, Hamburger and Lev,[20] Cottrell and Wood[21]) and also in normal persons[22] (Wenckebach[23]).

5. Abnormally intense discharges of epinephrine and related substances[24] into the blood stream during physical exercise in angina patients[25]

6 The presence of abnormally high concentrations of epinephrine and related substances in the heart muscle of patients who have suffered from anginal symptoms[26]

7. The analogy between the effects of epinephrine on the electrocardiogram and the electrocardiographic changes occurring during anginal attacks (Vesa,[27] Lepeschkin,[28] Katz, Hamburger and Lev[20] and others).

8 The occurrence of anginal symptoms in patients with adrenal medullary tumors (Bauer,[29] Nuzum and Dalton,[30] Brunschwig, Humphreys and Roome[31] and others) and their disappearance after removal of the tumor (Lenhartz[32]).

9 The provocation of anginal symptoms by agents which are known to stimulate the secretion of epinephrine, such as insulin (Brandt and Katz,[33] La Barre and Houssa,[34] Kugelmann,[35] Raab,[36] Schonbrunner[37]) and tobacco smoking (Cannon, Aub and Binger,[38]

Stewart and Rogoff,[39] Kobro,[40] Raab,[36] Külbs,[41] Deneke,[42] Strauss[43]).

10. The prolonged absence of anginal symptoms paralleling the disappearance of the abnormal discharges of epinephrine in angina patients following roentgen irradiation of the adrenal region[23] (Hutton,[44] Hadorn,[45] Schittenhelm,[46] Lippross,[47] Raab and Soule[48]).

It is well known that the thyroid hormone sensitizes the heart to the effects of epinephrine (Steppuhn, Naumova and Ugarova,[49] Wise and Hoff,[50] Aumann and Youmans,[51] Sawyer and Brown,[52] Sadae,[53] Lütolf[54]). In recent experiments a striking increase in the cardiac mortality of rats resulting from the injection of epinephrine was brought about by pretreatment with thyroxin, and a number of thyroxin

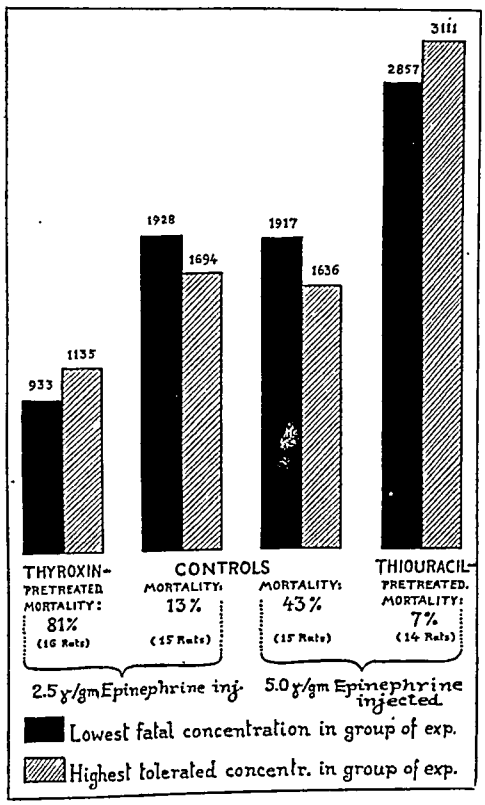

Fig. 1.—Accumulation of injected epinephrine in the heart muscle of the rat. The columns and figures represent the total colorimetric readings in the heart muscle (method explained in articles referred to in footnote 18 and in second reference in footnote 24). They include the basic concentration of epinephrine, sympathin and related substances plus the amounts of epinephrine accumulated following injection, partly in a chemically modified form. These experiments demonstrate the sensitization of the heart to epinephrine through thyroxin and the opposite, heart-protecting effect of thiouracil.

pretreated animals succumbed to myocardial accumulations of epinephrine which were considerably below the minimum level which had been found to be fatal in normal rats[55] (fig. 1). Furthermore, angina pectoris is a not uncommon complication of hyperthyroidism (Lev and Hamburger,[56] Brill[57]).

The observations of Riseman, Gilligan and Blumgart,[58] concerning an unchanged effect of intravenously injected epinephrine on blood pressure, pulse rate and systemic oxygen consumption in angina patients before and after thyroidectomy (except in cases of fully developed hypothyroidism) are not dealing with the criteria of angina pectoris (i. e. paroxysmal myocardial anoxia). Consequently they cannot be held against a fundamental role of epinephrine in the mechanism of angina pectoris. The theory that I[58a] have advanced maintains that the anginal symptoms on effort, emotion, exposure to cold and the like are caused essentially by the locally anoxiating effect of acute excess accumulations of epinephrine and sympathin in the heart muscle whose coronary arteries are sclerotic and which is sensitized to epinephrine through the thyroid hormone.

Thiouracil, as an agent which selectively suppresses the formation of thyroxin in the thyroid gland (Astwood[59]), appeared theoretically as a possible substitute for total thyroidectomy, whose shortcomings (risks of surgical intervention, irreparable loss of thyroid function) prevented its general acceptance.

It could be shown in recent experiments on rats that the sensitivity of the heart to epinephrine is much reduced after pretreatment with thiouracil and that considerably larger myocardial accumulations of epinephrine are tolerated by thiouracil treated rats compared with untreated animals[55] (fig. 1).

Also the epinephrine sensitivity of the heart of 10 physically healthy persons was found diminished after three months of thiouracil administration regarding pulse rate and anoxic changes of the electrocardiogram, while the blood pressure reactions were not significantly altered.[60]

Beginning in October 1943 thiouracil[61] was given to 10 patients with typical angina on effort. The patients were urged to keep a record of the daily number of their attacks on calendar sheets. When these records were kept in a negligent fashion the approxi-

date number of attacks was estimated from the patient's description.

Periods of thiouracil treatment of 6 patients were followed by or alternated with periods of placebo administration without the patients' knowledge.

Leukocyte counts were taken at weekly intervals during the early stages of the treatment and later on at increasingly longer intervals.

REPORT OF CASES

CASE 1 (fig. 2).—E. P., a woman aged 63, a housewife, had no serious illnesses previous to the onset of anginal symptoms seven years before. These increased gradually in intensity and number until a maximum was reached, which had persisted during the past three years without interruption. Two to five attacks of several minutes' duration occurred every day, consisting of a painful oppression underneath the sternum and in both shoulders. They were elicited by the slightest physical exertion, such as housework and walking, and furthermore by emotions and exposure to cold. At times they also occurred during bed rest.

There was a slight enlargement of the heart to the left and accentuation of the second aortic sound but no murmurs; the blood pressure was 185/102, the pulse rate 84. The basal metabolic rate was +24 per cent.

Thiouracil was given during seven weeks, first 1.0 Gm. daily in five doses, later 0.6 Gm. daily in three doses. The anginal symptoms improved decidedly within about ten days. The basal metabolic rate fell to +9 per cent and +4 per cent. The patient was soon able to do her housework and to walk uphill without trouble, except for a few isolated spells of pain at increasing intervals. The electrocardiogram became practically normal within two weeks (fig. 3). Discontinuation of the medication was followed by a slowly developing but only partial relapse, while the basal metabolic rate returned to a level of +25 per cent within eleven weeks. A second period of thiouracil medication (six weeks) caused a rapid fall of the basal metabolic rate to —3 per cent and an almost complete disappearance of the anginal symptoms persisting for another month after the thiouracil tablets had been replaced by placebos. Subsequently, while placebos were given over a total period of eleven months, the anginal symptoms reappeared slowly. However, the attacks remained much less frequent than before treatment, even when the basal metabolic rate had returned toward its original level and the electrocardiogram showed renewed signs of myocardial anoxia (fig. 5).

CASE 2 (fig. 3).—J. G., a man aged 70, an inmate of the "city farm," who had syphilis at the age of 46, "radically" treated, suffered during the past four years from attacks of pain underneath the sternum radiating into the left shoulder and arm, of two to three minutes' duration, sometimes longer; they occurred on walking, emotions, exposure to cold, after meals and now and then at rest; he had one or more attacks almost every day. Eight months before he had one very severe

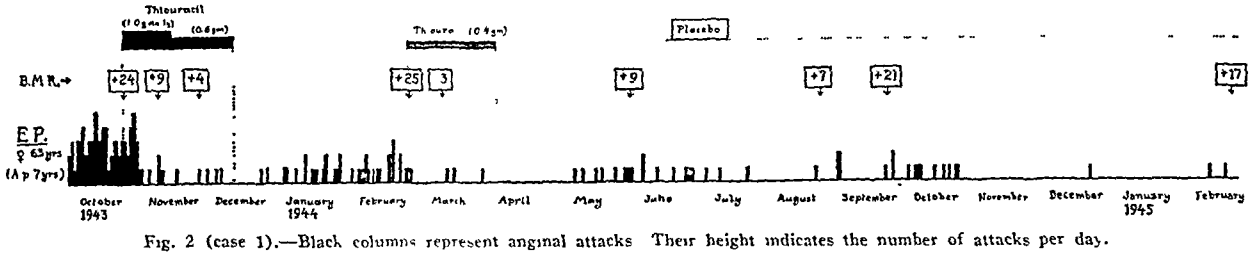

Fig. 2 (case 1).—Black columns represent anginal attacks. Their height indicates the number of attacks per day.

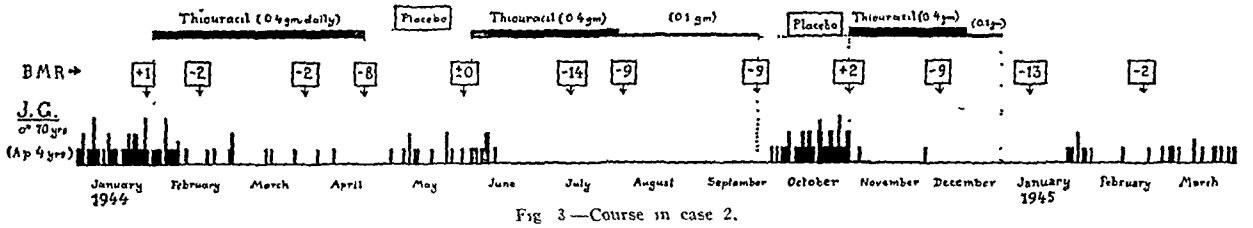

Fig. 3.—Course in case 2.

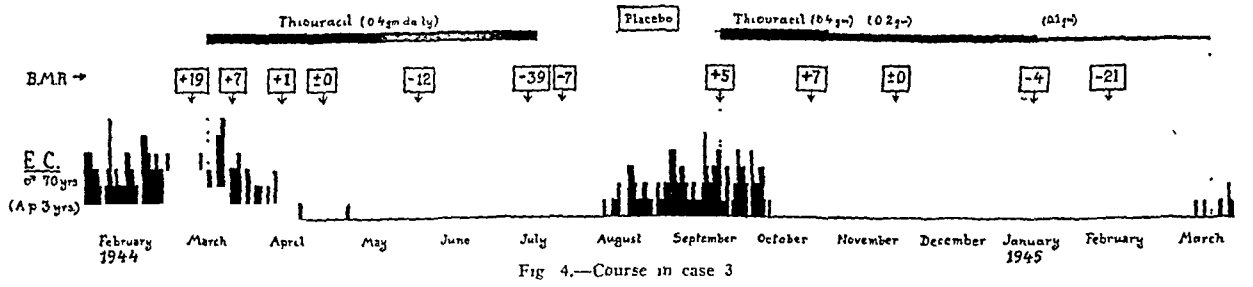

Fig. 4.—Course in case 3.

The patient was sent to the hospital in a state of collapse following a severe attack of pain. The heart was of normal size and shape; the blood pressure was 140/84. The electrocardiogram showed rate 61, low voltage, QRS notched, prominent Q_3, no upward deflection in lead 4, $T_{1,4}$ inverted, $T_{2,3}$ low. The basal metabolic rate was +1 per cent.

The patient received three periods of thiouracil treatment of three, four and two months' duration respectively, each with a dose of 0.4 Gm. daily at the beginning, later being reduced to 0.1 Gm. daily. During the first period of treatment the anginal attacks became quite infrequent within about two weeks; during the two following periods of treatment they disappeared rapidly and almost completely. The patient was now able to walk and climb stairs without discomfort. During each period of treatment the basal metabolic rate fell 7, 14 and 11 points respectively. When it was at its lowest the face appeared slightly puffy, he complained of sleepiness and the blood cholesterol was 330 mg. per hundred cubic centimeters (Aug. 2, 1944). Reduction of the dose to 0.1 Gm. abolished the myx-

edematous features without reappearance of the anginal complaints. Each period of treatment was followed by several weeks of placebo administration without the patient's knowledge. In each instance the anginal symptoms reappeared in either partial or full relapses together with a return of the basal metabolic rate to its original level. The electrocardiogram remained unchanged throughout.

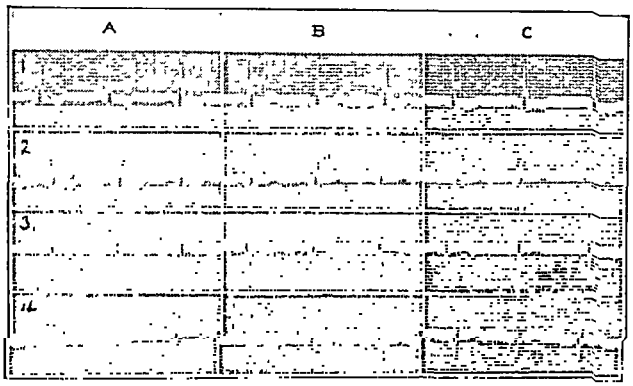

Fig. 5 (case 1).—*A*, untreated; severe anginal attacks; basal metabolic rate + 24 per cent. *B*, thiouracil (two weeks); almost symptom free; basal metabolic rate + 9 per cent. *C*, placebo (eleven months); partial relapse; basal metabolic rate + 17 per cent.

CASE 3 (fig. 4).—E. C., a man aged 70, without occupation previously in good health, during the past three years had attacks of severe pain in the epigastrium and under the lower part of the sternum, often accompanied by numbness in the arms, occurring on the slightest exertion (he could not walk farther than 50 feet without stopping) and also if exposed to cold. The pains persisted usually for about five minutes and occurred several times daily.

The heart was slightly enlarged to the left; the aortic second sound was accentuated; there was a systolic murmur over the entire heart. The blood pressure was 190/110. The basal metabolic rate was + 19 per cent.

Thiouracil was given in two periods of four months' and five months' duration respectively, during the first period 0.4 Gm. daily, during the second period 0.4 Gm. daily at the beginning, later 0.2 and 0.1 Gm. daily. During the first period the attacks disappeared within one month, except for two more isolated attacks; during the second period about three weeks elapsed before the attacks disappeared completely. The patient was now able to walk and climb hills at a fast pace without any discomfort. During the first period of treatment the basal metabolic rate fell to — 39 per cent and typical myxedematous features developed. The blood cholesterol was 311 mg. per hundred cubic centimeters at this time. During the second period the basal metabolic rate fell to a minimum of — 21 per cent; the blood cholesterol was 368 mg. per hundred cubic centimeters but puffiness and sleepiness were much less pronounced with the smaller dosage.

Between the two periods of medication a nine week period of unconscious placebo intake was interpolated during which the basal metabolic rate rose rapidly although not quite to its original level, and the attacks reappeared in almost full force within three weeks.

The electrocardiogram (fig. 6) showed at first increasing pathologic changes (depression of $ST_{1,2}$, diphasic T_1, flattening of T_4) at a time when anginal symptoms were completely absent. During the following placebo-induced relapse these changes were even more accentuated, but they gradually subsided during the second period of treatment, at the end of which the electrocardiogram was about the same as at the beginning.

CASE 4 (fig. 7).—W. J. L., a man aged 68, formerly a carpenter, had previously been in good health. During the past two years a sensation of oppressing "fulness" was felt underneath the sternum once or several times daily on walking and emotions. It usually stayed on for four to five minutes and compelled the patient to stand still.

There was a moderate degree of pulmonary emphysema. The heart was slightly enlarged to the left; there was a systolic murmur over the entire heart. The blood pressure was 130/68. The electrocardiogram showed rate 67, PR 0.23 second; T_3, inverted. The basal metabolic rate was — 4 per cent.

The patient received liver injections from time to time because of soreness of the tongue. There was no anemia.

Thiouracil 0.4 Gm. daily in four doses was given during three and a half months. The basal metabolic rate fell gradually to — 27 per cent. When it had reached — 14 per cent after about two weeks the anginal attacks became very infrequent and from the sixtieth day on they ceased completely. The patient was now able to walk without discomfort and to do strenuous work, such as lawn mowing and carrying wood. The blood cholesterol level was 284 mg. per hundred cubic centimeters. Under placebo administration the basal metabolic rate remained low (— 9 to — 24 per cent) for six months. After seven months, when the basal metabolic rate had risen to + 9 per cent, anginal symptoms reappeared in a mild form. The electrocardiogram remained unchanged throughout.

CASE 5 (fig. 8).—R. M., a woman aged 43, a housewife, during the past nine months had suffered from attacks of heavy, painful pressure underneath the sternum, expanding into the left shoulder and arm, sometimes also into the left jaw. These were elicited by walking, emotions and cold wind and occurred several times daily, lasting several minutes.

The heart was slightly enlarged to the left. The aortic second sound was accentuated. The blood pressure was 212/112. There was occasionally some shortness of breath on exertion without other signs of cardiac decompensation. The menstruation had been irregular during the last half year.

The electrocardiogram showed rate 81, PR 0.20 second, QRS_1 0.15 second, QRS_2 0.11 second, ST_1 depressed, ST_3 elevated, left axis deviation and left sided bundle branch block. The basal metabolic rate was + 27 per cent.

Thiouracil 0.4 Gm. daily in four doses was given continually during five and one-half months with an interruption of one week. The basal metabolic rate responded only to a moderate degree, the lowest level reached being + 14 per cent. It later returned to + 26 per cent under continued medication. A

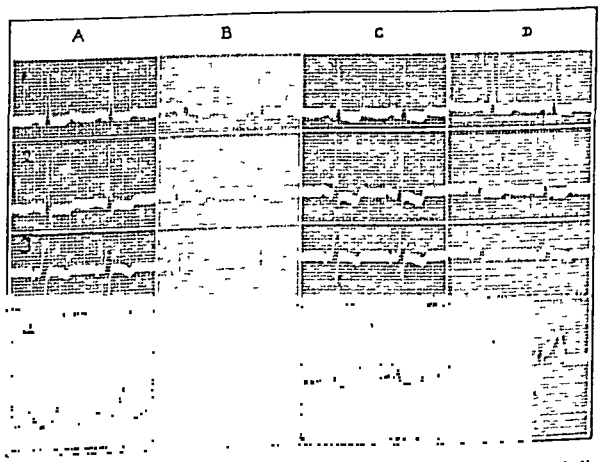

Fig. 6 (case 3).—*A*, untreated; severe anginal attacks; basal metabolic rate + 19 per cent. *B*, thiouracil (four months); symptom free; basal metabolic rate — 39 per cent. *C*, placebo (two months); complete relapse; basal metabolic rate + 5 per cent. *D*, thiouracil (four months); symptom free; basal metabolic rate — 4 per cent.

slight improvement of the anginal symptoms was reported, beginning after five weeks of medication. The patient could walk with greater ease and on many days had no symptoms at all, but the improvement remained only partial. During a subsequent six week period of placebo administration the condition grew worse again. Two series of x-ray irradiation of

the adrenal region at a seven week interval were finally followed by an almost complete disappearance of the anginal symptoms. The electrocardiogram and blood pressure remained practically unchanged until a coronary occlusion occurred three months later.

CASE 6 (fig. 9).—J. K., a man aged 62, an employee, previously in good health, one year before examination had a coronary infarction. Since then he suffered from attacks of a "burning oppression" spreading from the epigastrium to the substernal area, sometimes accompanied by numbness of the left arm. The attacks occurred once to a few times daily on walking, emotions, after meals, rarely at rest. They lasted a few seconds to minutes.

The heart was normal to percussion and auscultation. Blood pressure was 135 systolic; the diastolic pressure was indistinct. The electrocardiogram showed rate 65, PR 0.22 second, left axis deviation, QRS notched, T flat in all leads. The basal metabolic rate was —9 per cent.

Thiouracil 0.4 Gm. daily in two doses was given during four and one-half months. The symptoms began to improve after six weeks of treatment and then disappeared completely. Physical exertion was no longer accompanied by any discomfort after one month of treatment. The basal metabolic rate had fallen to +11 per cent at this time. Pains became quite infrequent (only about once or twice a week at heavier work) and were much less intense. Walking caused only rare and little discomfort. The basal metabolic rate fell to ±0 per cent and finally, at the end of the fourth month, to —3 per cent. At this time she appeared slightly puffy and the blood cholesterol was 619 mg. per hundred cubic centimeters.

CASE 8.—G. C., a man aged 69, without occupation, who previously had been in good health, during the past four years felt an oppressing substernal pain on walking, climbing, emotions, exposure to cold, sometimes after meals. These attacks, which occurred several times per week, lasted from a few minutes to one hour. Seven months before the patient suffered a cerebral accident with temporary hemiplegia.

The heart was slightly enlarged to the left. There was a loud systolic murmur. The blood pressure was 192/88. The spinal column showed a pronounced degree of hypertrophic arthritis. The basal metabolic rate was +16 per cent. The electrocardiogram is reproduced in figure 11.

Thiouracil 0.4 Gm. daily in two doses was given during four months with an interruption of three weeks. Within about

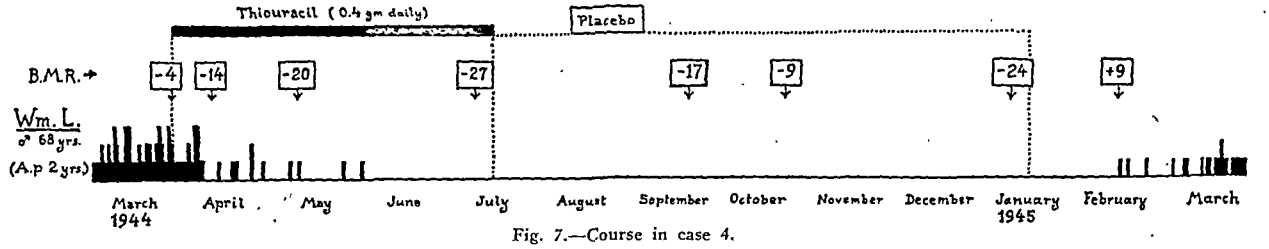

Fig. 7.—Course in case 4.

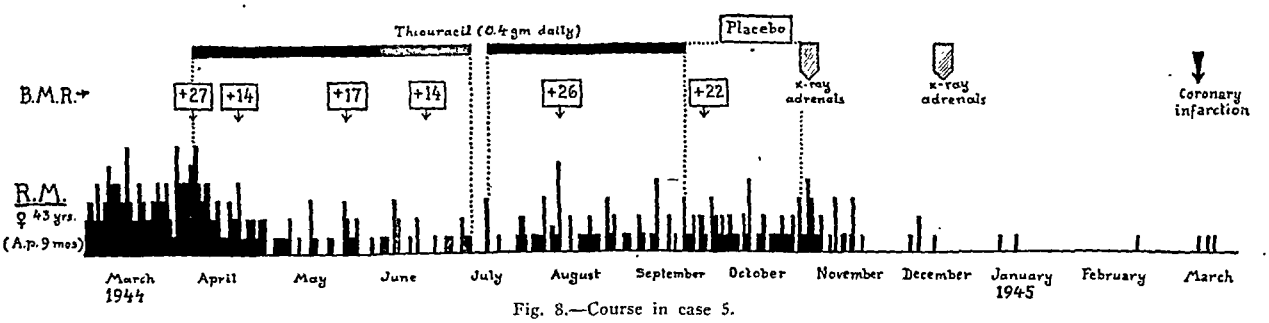

Fig. 8.—Course in case 5.

during the last two months of treatment. The basal metabolic rate began to fall only after two and one-half months. When it reached a lowest point of —19 per cent the patient appeared somewhat pasty and complained of a slight degree of sleepiness and fatigue and of an unpleasant taste "like iron." The blood cholesterol was 419 mg. per hundred cubic centimeters at this time. Replacement of thiouracil by placebos without the patient's knowledge was followed by an almost complete relapse within two weeks. The basal metabolic rate rose to +2 per cent within about three weeks. The electrocardiogram remained unchanged.

CASE 7 (fig. 10).—R. L., a woman aged 67, a housewife, who had had diabetes for the past fifteen years (daily 40 units of protamine zinc insulin), hypertension and headaches for the past six years, during the last two years had to complain of substernal pain, irradiating into the left shoulder, jaw and arm on any kind of exertion, even light housework, and furthermore on exposure to cold and on emotions. The pains occurred several times daily, lasting a few minutes to hours.

The heart was moderately enlarged to the left. The blood pressure was 225/98. The electrocardiogram showed rate 78, left axis deviation, ST_1 slightly depressed, ST_3 slightly elevated, T_1 inverted. The basal metabolic rate was +32 per cent. Thiouracil 0.4 Gm. in 2 doses was given daily during four months. An improvement of the anginal symptoms was noticed three weeks, when the basal metabolic rate had fallen to +7 per cent, the symptoms began to improve and the patient walked and climbed much more easily. This improvement made further progress during the entire period of treatment, and he frequently took long walks, even in very cold weather. There were still pains "from time to time" but they were no longer elicited by exertion. They were only quite mild and of a dull, aching character, which seemed to be attributable to the spinal arthritis rather than to the coronary condition. The patient stated repeatedly in writing that he felt "lots better."

The basal metabolic rate fluctuated during the first three months (+14, +7, +10, +9, +5, +12 per cent) but finally fell to —5 per cent. At this time he appeared slightly puffy and the blood cholesterol was 442 mg. per hundred cubic centimeters.

CASE 9.—R. H., a man aged 62, an undertaker, previously in good health, had during the past three years had anginal symptoms consisting of heavy substernal pressure on walking, climbing, emotions and exposure to cold wind, rarely at rest. The attacks occurred once or more daily and lasted a few minutes.

The heart was normal to percussion and auscultation. The blood pressure was 170/100. The electrocardiogram showed left axis deviation but otherwise was normal. The basal metabolic rate was —2 per cent.

Thiouracil 0.4 Gm. daily in four doses was given during three months. The anginal symptoms remained essentially unchanged, although the patient claimed that he felt "a little better with slightly diminished frequency and intensity of the attacks." The basal metabolic rate also remained practically unchanged (—2, +2, +3 per cent). After three months of medication he suddenly collapsed and died at a funeral which he was conducting, obviously from coronary occlusion. No autopsy was performed.

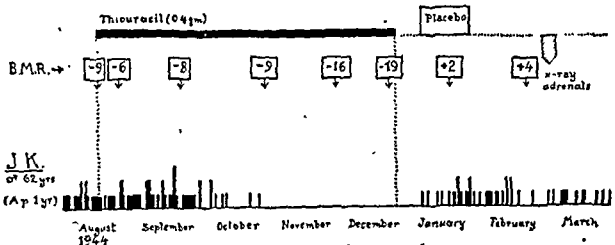

Fig. 9.—Course in case 6.

CASE 10.—M. N., a woman aged 57, a housewife, with old tuberculosis of the spine and mild diabetes, during the past four years had had attacks of pain across the chest, irradiating into both arms, lasting from a few minutes to one hour or more. These attacks occurred two to six times daily on walking, emotions or exposure to cold wind and frequently also at rest. There had been repeated episodes of cardiac decompensation with dyspnea, orthopnea, cyanosis and edema, controlled each time by digitalis. Roentgen irradiation of the adrenal region in April and December 1940 had been followed by partial improvement of the anginal symptoms of about two years' duration, until a complete relapse occurred in September 1942.

The heart was enlarged to the left. There was a systolic murmur over the entire heart. The aortic second sound was accentuated. The blood pressure was 210/120. The electrocardiogram showed rate 76, left axis deviation, $T_{1,2}$ flat, T_3 inverted, T_4 invisible. The basal metabolic rate was +3 per cent.

Thiouracil was given during four weeks, first 0.8 Gm. daily in four doses for three weeks, then 1.2 Gm. daily for one more week. During this treatment the basal metabolic rate remained practically unchanged (+3, +1, —1 per cent) and also the anginal attacks continued unabated. Two days before conclusion of the treatment there occurred a number of unusually severe attacks with electrocardiographic evidence of a posterior wall coronary occlusion. Death followed eight days later. No autopsy was performed.

COMMENT

Thiouracil medication proved therapeutically effective in 8 out of 10 patients with angina pectoris. In 4 cases, 3 of which can be classified as severe, the

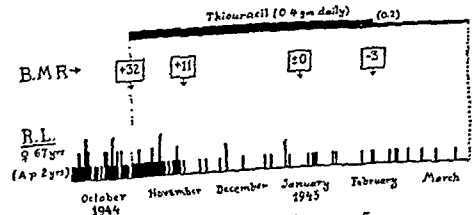

Fig. 10.—Course in case 7.

symptoms disappeared entirely during the treatment. When the drug was replaced by placebo tablets without the patient's knowledge, partial or complete relapses occurred within a matter of weeks or months in these 4 cases.

Definite improvement regarding the frequency and intensity of the anginal symptoms occurred in 3 cases. In 1 of them the treatment was followed by placebo administration, leading to a partial relapse.

One patient was only slightly improved, but two subsequent series of roentgen irradiations of the adrenal region brought the symptoms to almost complete disappearance.

Two patients with severe angina pectoris died from coronary occlusion, while the treatment was still under way, without having experienced an improvement of their symptoms.

The dosage ranged between 1.2 Gm. (1 case) and 0.4 Gm. per day in divided doses at the beginning of the treatment to 0.1 Gm. daily as a maintenance dose.

The onset of subjective improvement was reported after ten days to six weeks of medication. If thiouracil was given in a second or third period following placebo-induced relapses, improvement and disappearance of symptoms occurred more rapidly.

A significant decrease of the basal metabolic rate was observed in the 7 decidedly or completely improved patients, rather closely paralleling the diminution or disappearance of the anginal symptoms. No significant lowering of the basal metabolic rate occurred in

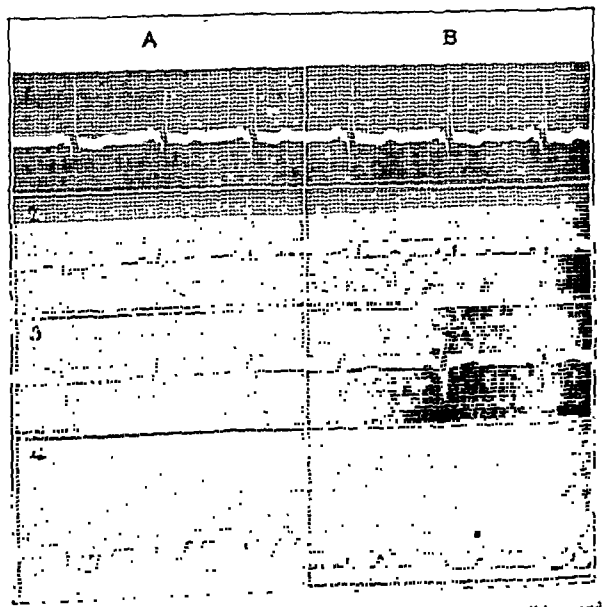

Fig. 11 (case 8).—*A*, untreated; anginal symptoms on walking and other effort; basal metabolic rate +16 per cent. *B*, thiouracil (four months); considerably improved; no more pain on walking; basal metabolic rate —5 per cent.

the 2 nonresponding patients who died, and only a moderate and temporary fall was observed in the 1 patient who was only slightly improved.

Maximum improvement was reached when the basal metabolic rate had fallen 7 to 27 points below its original level, as shown in the table. Relapses occurred simultaneously with a return of the basal metabolic rate toward its pretreatment level. In case 4 the basal metabolic rate remained for six months far below the pretreatment level and there was freedom from symptoms during this entire period. In case 2 analogous developments required only a few days.

The initial basal metabolic level at the time of introduction of the thiouracil treatment had no apparent influence on the efficacy of the medication. It ranged between +32 and —9 per cent. In none of the 10 patients were there any indications of hyperthyroidism. High basal metabolic levels are not unusual in hypertensive patients (e. g. patients 1, 5 and 7). They are probably of hypothalamic origin.[62]

62. Raab, Wilhelm: Hypermetabolic Hypertension: A Syndrome of Central Nervous Origin, to be published.

Fully developed myxedema resulted in case 3; in cases 2, 6, 7 and 8 there was some puffiness of the face, in 2 of them combined with sleepiness, when the basal metabolic rate had reached its lowest level. These phenomena disappeared spontaneously within one to two weeks after discontinuation or reduction of the thiouracil medication. The blood cholesterol was elevated during the hypothyroid episodes.

The electrocardiogram was rapidly normalized in case 1 and remained so for about six months of placebo administration until the basal metabolic rate returned to its former level. A partial normalization of the electrocardiogram occurred also in case 8 together with clinical improvement. In case 13, on the other hand, the pathologic changes of the electrocardiogram became even more pronounced during the first thiouracil period than before treatment. They reached a maximum during a severe relapse under placebo administration but reverted to the original degree when the patient became again symptom free during a second thiouracil period. In the other cases no significant changes of the electrocardiogram were noted.

The behavior of the blood pressure was uncharacteristic.

No untoward side effects of the thiouracil medication were observed in any case.

bolic rate and symptomatic response is the fundamental involvement of even the normal thyroid function in the mechanism of a probably large group of angina pectoris cases. That this involvement consists essentially of a sensitization of the heart muscle to the anoxiating action of epinephrine and probably also of sympathin originating in the heart itself is suggested by many clinical and experimental facts as outlined in the introduction.

Failure of anginal symptoms to respond to thiouracil, as in cases 9 and 10, may be due to the rather wide individual differences regarding the effect of thiouracil on the human thyroid gland as described by Astwood.[59] On the other hand, even complete absence of thyroid function, as in total thyroidectomy, does not always abolish the anginal symptoms (Claiborne and Hurxthal[4] and others). The degree of coronary stenosis, of the intensity of epinephrine discharges and other factors may be responsible for these differences of therapeutic results. In 1 case that I observed anginal symptoms persisted after total thyroidectomy despite the development of myxedema. Two others with spontaneous myxedema also showed typical angina pectoris.

Elaboration of an ideal dosage of thiouracil both for initial treatment of angina pectoris and for maintenance of an established improvement will require further pro-

* Points.

The therapeutic results obtained with thiouracil so far are similar to those described after thyroidectomy by Blumgart and his associates,[2] Levine and Eppinger[3] and others. These workers found a basal metabolic level of about —20 per cent most favorable regarding prevention of both anginal symptoms and of troublesome myxedematous features. The prompt disappearance of myxedematous phenomena with discontinuation or reduction of thiouracil is one of the advantages of this reversible "functional thyroidectomy" over the irreversible surgical procedure, which often requires substitutive thyroid medication.

The coincidence of symptomatic response and of response of the basal metabolic rate to thiouracil was quite striking. However, this cannot be considered as proof of the conception that the presence or absence of anginal symptoms is directly determined by the rate of systemic oxygen consumption. This conception has been questioned also in regard to the effect of thyroidectomy by Eppinger and Levine[8] and by Scherf.[6] According to Leblond and Hoff[63] the effect of thyroxine on the heart is a direct one and not the consequence of general metabolic stimulation.

The only fact which can be concluded from the approximate parallelism of changes in the basal metabolic rate and symptomatic response is the fundamental involvement of even the normal thyroid function in the mechanism of a probably large group of angina pectoris cases. That this involvement consists essentially of a sensitization of the heart muscle to the anoxiating action of epinephrine and probably also of sympathin originating in the heart itself is suggested by many clinical and experimental facts as outlined in the introduction.

Failure of anginal symptoms to respond to thiouracil, as in cases 9 and 10, may be due to the rather wide individual differences regarding the effect of thiouracil on the human thyroid gland as described by Astwood.[59] On the other hand, even complete absence of thyroid function, as in total thyroidectomy, does not always abolish the anginal symptoms (Claiborne and Hurxthal[4] and others). The degree of coronary stenosis, of the intensity of epinephrine discharges and other factors may be responsible for these differences of therapeutic results. In 1 case that I observed anginal symptoms persisted after total thyroidectomy despite the development of myxedema. Two others with spontaneous myxedema also showed typical angina pectoris.

Elaboration of an ideal dosage of thiouracil both for initial treatment of angina pectoris and for maintenance of an established improvement will require further prolonged observations. From the cases reported it would seem that a dosage quite similar to that in hyperthyroidism will be adequate: 0.4 Gm. daily for a few weeks or months followed by a maintenance dose of 0.2 or 0.1 Gm. daily over longer periods of time and eventually tentative discontinuation of the drug. Doses larger than 0.6 Gm. per day should be avoided in view of the possibility of untoward side effects as described in the literature on thiouracil.

Whether or not the elevation of the blood cholesterol level which is likely to result from thiouracil medication has to be regarded as a serious disadvantage, considering a possible enhancement of coronary sclerosis, can be decided only on the grounds of much larger and prolonged series of observation. According to Shaffer[64] a significant role of cholesterolemia in the origin of coronary sclerosis is doubtful.

The objection usually raised against claims of therapeutic results in angina pectoris, that they are "psychogenic" or "imaginary," cannot be upheld against the results of thiouracil treatment in view of the clear-cut relapses occurring under unconscious placebo medication.

The therapeutic efficacy of thiouracil in angina pectoris makes this drug appear as a valuable and preferable substitute for thyroidectomy, and it constitutes a

64. Shaffer, C. F.: The Nutritional Role of Cholesterol in Human Coronary Arteriosclerosis, Ann. Int. Med. **20**: 948, 1944.

further step in the clarification of the pathogenesis of angina pectoris as a phenomenon of hormonal chemical interference in myocardial metabolism.

All prolonged therapeutic successes which were reported, up to the present, as being achieved in angina pectoris by therapeutic measures influencing the endocrine system can be explained as being due to a diminution of the acutely anoxiating effect of epinephrine and sympathin on the myocardium whose blood supply is curtailed by coronary sclerosis:

1. Thyroidectomy decreases the sensitivity of the heart to epinephrine (Sawyer and Brown,[52] Eppinger and Levine,[8] Shambaugh and Cutler [9]).

2. Thiouracil, by suppressing the formation of thyroid hormone, acts in the same manner, as evidenced by experiments on animals and man.[65]

3. Roentgen irradiation of the adrenal region (Raab,[22] Hutton,[44] Hadorn,[45] Schittenhelm,[46] Lippross,[47] Raab and Soule [48]) abolishes the abnormally intense discharges of epinephrine and related compounds which are a characteristic of angina patients.[25]

4. Testosterone propionate (Hennsge,[66] Pick,[67] Arndt,[68] Walker,[69] Bonnell, Pritchett and Rardin,[70] Lesser,[71] Hamm,[72] McGavack [73]) normalizes the myocardial metabolic changes which follow on castration (Schumann [74]) and which seem to be due to the presence of increased amounts of epinephrine in the heart muscle.[18] They are qualitatively identical with those elicited by epinephrine (Schumann [74]).

The traditional but inadequate explanations of angina pectoris as a manifestation of acute myocardial anoxia caused by "overwork" or "coronary spasm" served their purpose as long as nothing was known about myocardial metabolism and the fundamental role of neurohormonal factors in its physiologic and pathologic aspects. These factors are becoming increasingly apparent and are likely to make some of the customary mechanistic hypotheses obsolete.

SUMMARY

Treatment with thiouracil proved effective in 7 out of 10 patients with angina pectoris, 4 of whom became entirely symptom free during the treatment. One patient was only slightly improved. Two patients remained unimproved and died from coronary occlusion.

Clinical improvement coincided rather closely with the fall of the metabolic rate and failed to occur in those patients whose basal metabolic rate did not decrease.

Replacement of thiouracil by placebos without the patient's knowledge was followed by a partial or complete recurrence of the anginal symptoms, coinciding with a return of the basal metabolic rate toward its former level within ten days to seven months following discontinuation of the thiouracil medication.

The thyroid hormone, even in physiologic amounts, sensitizes the heart muscle to the anoxiating toxic action of epinephrine. Thiouracil exerts an opposite, heart-protecting effect, obviously through suppression of thyroid hormone formation.

In view of these and many other experimental and clinical facts the efficacy of "functional thyroidectomy" through thiouracil is ascribed to a diminution of myocardial sensitivity to heart-anoxiating, angina-producing epinephrine and sympathin discharges.

WHY USE SPINAL ANESTHESIA?

URBAN H. EVERSOLE, M.D.
BOSTON

Many reasons have been advanced for using spinal anesthesia, ranging from pure convenience to increased safety for the patient. This type of anesthesia has been utilized for every type of operation, from removal of warts and ingrown toenails to craniotomy. As with other forms of anesthesia, too much emphasis has been placed on the selection of the agent and method rather than on the skill and experience of the one responsible for the administration.

This form of anesthesia is so generally and successfully employed for surgery of the lower part of the abdomen and the extremities that its use for surgery in these areas will not be considered in this paper. On the other hand, the utilization of spinal anesthesia for surgery of the chest, head and neck is considered to be fraught with too many dangers to allow for its general use. This discussion, therefore, will be limited to an attempt to give an answer to the question "Why use spinal anesthesia for upper abdominal surgery?" Irrespective of how many other reasons or excuses may be advanced for the use of spinal anesthesia for surgery in the upper part of the abdomen, the most important one is that a completely successful spinal anesthesia gives working conditions in the abdomen unexcelled and rarely equaled by other methods. Usually all other reasons play a secondary role to this one. Assuming this statement to be correct and that next to the elimination of the actual pain of surgery, with as little disturbance of physiologic processes as possible, the most important function of any anesthesia is to facilitate the work of the surgeon, it would seem to follow naturally that, unless there were important disadvantages and deleterious side effects, spinal anesthesia would be the natural choice for practically all abdominal surgery.

Unfortunately there are several disadvantages and undesirable side effects of spinal anesthesia that, until means could be devised for circumventing or nullifying them, made the selection of this method for upper abdominal surgery often unwise. Many of these objections apply to the use of spinal anesthesia in general, while others have a more special significance when the anesthesia is intended for operations in the upper part of the abdomen.

The disadvantages of spinal anesthesia which must be overcome before it can be employed with uniform success for surgery in the upper part of the abdomen are (1) difficulty in obtaining anesthesia sufficiently high to permit work in this area without discomfort to the patient and with adequate muscular relaxation, (2) insufficient duration of anesthesia necessitating a change

From the Department of Anesthesia, the Lahey Clinic.
Read before the Section on Anesthesiology at the Ninety-Fourth Annual Session of the American Medical Association, Chicago, June 14, 1944.

to a less satisfactory method during the course of the operation, (3) respiratory depression, (4) circulatory depression, (5) nausea, retching and vomiting during operation and (6) psychic objection on the part of the patient and even of the surgeon and anesthetist to the patient being awake during the operation.

The first three disadvantages and to some extent the fourth are closely related to the distribution of the spinal anesthetic agent in the spinal canal. The height or cephalad distribution of anesthesia is obviously a result of the presence of the agent in the spinal canal at the level from which the corresponding nerve roots arise. Frequently, however, it is not appreciated that the duration of spinal anesthesia at a certain level is to a great extent a direct function of the concentration of the agent. In order to have long lasting upper abdominal anesthesia, the maximum concentration of the agent must be along the nerve roots supplying the upper part of the abdomen and not at the spinal puncture site in the lumbar area. Another factor of great importance is that all of the nerve supply to the abdomen

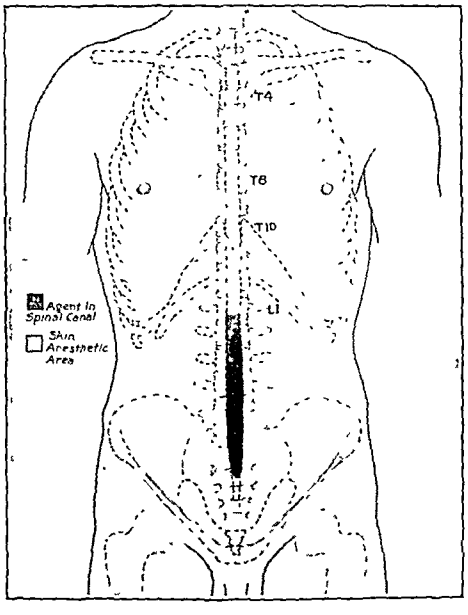

Fig. 1.—Anesthetic level necessary for perineal and lower extremity surgery.

arises in the thoracic segments of the spinal cord. This means that there is almost invariably some impairment of lower intercostal muscle activity with spinal anesthesia for abdominal surgery. Of course, the higher the anesthesia the more intercostal muscles are impaired. If the agent progresses cephalad to the first thoracic segment in sufficient concentration, all intercostal muscles become paralyzed. Paralysis of the diaphragm will ensue if the motor nerves are involved as high as the fourth cervical segment.

A review of some of the anatomic factors involved in the distribution of spinal anesthesia may be helpful in appreciating the problems associated with distributing the major portion of an anesthetic agent on the nerve roots to the upper part of the abdomen and at the same time stopping the agent short of respiratory paralysis. Figures 1, 2, 3 and 4 are representations of the distribution of the spinal anesthetic agent in the spinal canal with the corresponding sensory surface distribution of anesthesia. In order to have anesthesia to the groin, the anesthetic agent must be as high as the first lumbar segment (fig. 1). If the agent is advanced cephalad to the tenth thoracic segment, surface anesthesia will be present to the umbilicus (fig. 2). This level would permit surgery on the perineum, anus, extremities and superficial operations on the lower part of the abdomen.

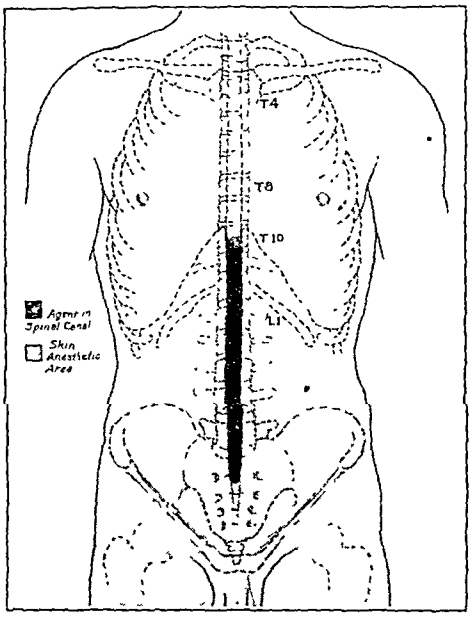

Fig. 2.—Anesthetic level necessary for superficial operations in the lower part of the abdomen.

With sensory anesthesia no higher than this, intra-abdominal operations could be performed only in the lower part of the abdomen and then without abdominal exploration or tension on the viscera. With the agent

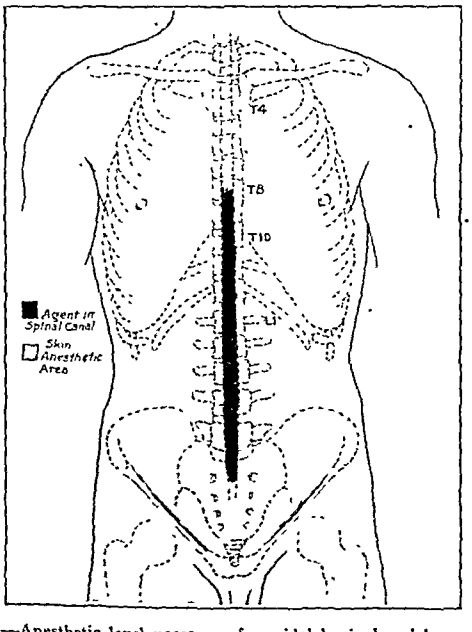

Fig. 3.—Anesthetic level necessary for midabdominal and lower abdominal surgery.

at the level of the seventh thoracic segment, the upper border of sensory anesthesia is at the costal margin (fig. 3). This is still not high enough to permit operations in the upper part of the abdomen or complete abdominal exploration. Completely satisfactory anesthesia for operations such as hysterectomy or appen-

dectomy should not be lower than this. Satisfactory spinal anesthesia for upper abdominal surgery cannot be obtained until the agent has progressed cephalad to approximately the fourth thoracic segment. This gives surface anesthesia to the nipple line (fig. 4). To obtain anesthesia to the groin, in the average adult male

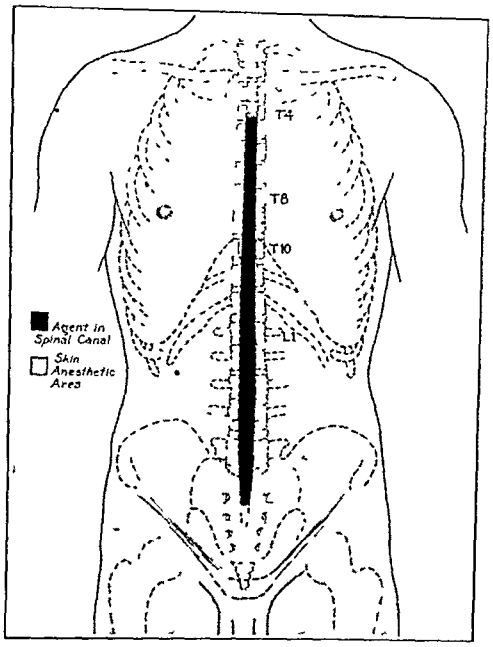

Fig. 4—Anesthetic level necessary for complete abdominal exploration and upper abdominal surgery.

patient the anesthetic agent must reach a level in the spinal canal approximately 18 cm. above the sensory skin level and 7.5 cm. above the usual site of injection (third lumbar interspace). For anesthesia to the level of the umbilicus, the agent is approximately 15 cm. above the skin anesthesia level and 12.5 cm. above the

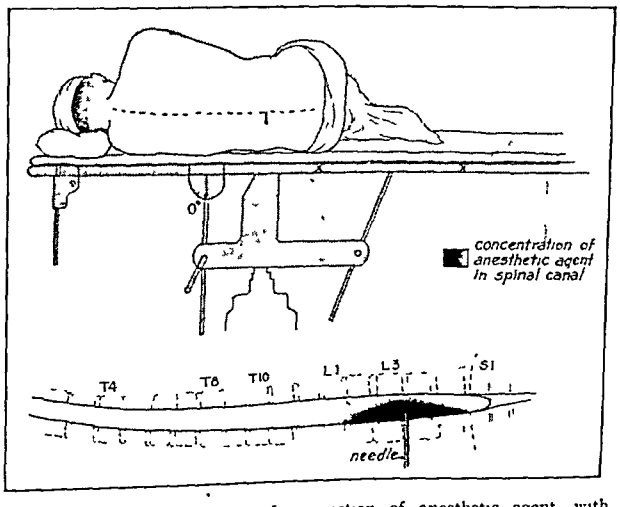

Fig. 5—Position of patient for injection of anesthetic agent, with diagram illustrating distribution of the anesthetic agent in the spinal canal immediately following injection, when diffusion or volume technic is employed

site of injection. If, however, we wish anesthesia to the nipple line for upper abdominal surgery, the agent must travel 26 cm. from the site of injection and will be 7 cm. above the superficial sensory level.

With surface anesthesia to the nipple line, the agent is present in the spinal canal approximately 14 cm. from that level, which may result in respiratory paralysis. This represents the average distance from the fourth thoracic segment to the fourth cervical segment (origin of the phrenic nerve) and leaves only the upper three or four intercostal muscles unaffected (fig. 6).

There are, of course, many factors that influence the distance an anesthetic agent will progress cephalad in the spinal canal. The site of injection often is thought to play an important part in the height of spinal anesthesia. While this factor does play a minor role, it is relatively unimportant as long as the injection is made anywhere in the lumbar area. Other factors of importance are the volume of solution injected, the speed of injection, the amount of barbotage employed, diffusion and, finally, the influence of gravity when there is a difference between the specific gravity of the anesthetic

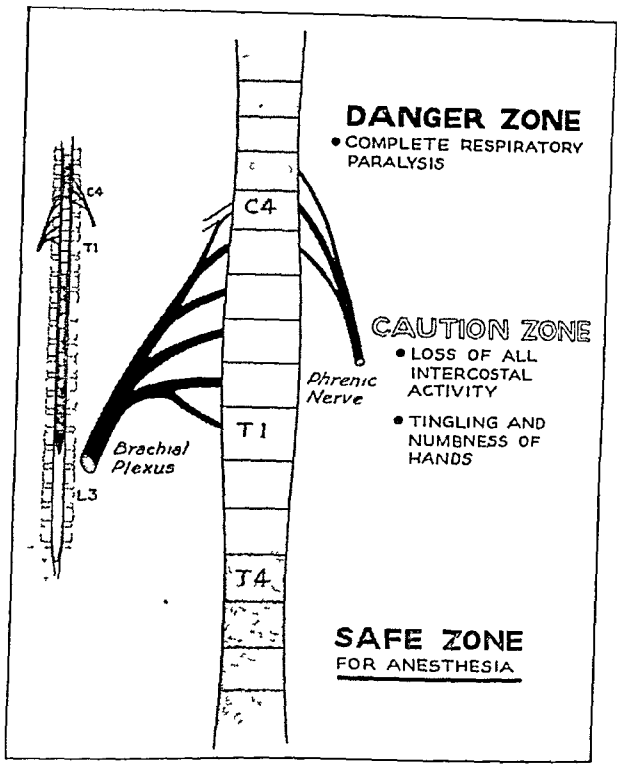

Fig. 6—Diagrammatic section of spinal canal. Note proximity of fourth thoracic segment (level necessary for satisfactory upper abdominal surgery) to origin of phrenic nerve.

solution and the spinal fluid. In addition, there are anatomic factors such as spinal curves and arachnoidal adhesions which may influence the distribution of the anesthetic agent in the spinal canal.

It is unfortunate that the factor usually depended on primarily for distribution of the anesthetic agent in the spinal canal is simple diffusion, a process over which little control can be exercised. When a spinal anesthetic mixture of approximately the same specific gravity as spinal fluid is employed or when the patient is kept level during and immediately following the injection of the agent, diffusion is the factor playing the greatest part in its distribution. However, volume and rate of injection are factors that must be considered. In any event the maximum concentration is at the site of injection, that is, in the lumbar area, which is the level from which the nerves to the lower extremities arise. It follows that the concentration is in inverse ratio to the distance from the site of injection. The

result is longer lasting anesthesia in the extremities, with a gradual decrease in the duration of anesthesia toward the head. Figure 5 is a representation of what is assumed to be the distribution of the agent in the spinal canal during and immediately following its injection, while figure 7 represents the later distribution of the agent with corresponding surface areas of anesthesia where a diffusion technic is employed.

It has been shown experimentally that a fluid with a higher specific gravity can be fairly accurately distributed in a glass tube containing fluid of a lower specific gravity. Clinical experience in employing this principle for more than 15,000 patients has shown that the spinal canal and its contained fluid can be treated almost as though it were a test tube. By maintaining a constant tilt of the operating table (head down from the horizontal) and using an anesthetic mixture of a constant specific gravity, always heavier than the spinal fluid, and a constant rate of injection in the same lumbar interspace, the height of anesthesia can be fairly accurately determined by employing only one variable. This variable is the time that the table and patient are kept in the head down position. By this

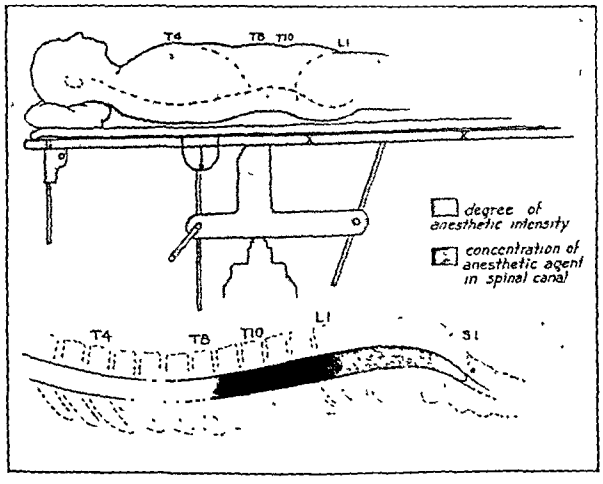

Fig. 7.—Distribution of the anesthetic agent in the spinal canal with corresponding areas of anesthesia intensity after anesthesia has been established, when diffusion or volume technic is employed

method the bulk of the anesthetic solution can be placed at the level desired to give the maximum concentration on the nerve roots supplying the area in which the operation is to take place. For exploration over the dome of the liver it must be as high as the fourth thoracic segment, and for operations on the stomach and gallbladder there must be a rather high concentration of the anesthetic agent as far up as the fifth or sixth thoracic segment.

If an innoxious substance with a fairly high specific gravity compared with that of spinal fluid (specific gravity 1.003 to 1.010) is mixed with the anesthetic solution, a mixture is obtained that is heavy enough to allow the agent to be carried cephalad by gravity more or less as a mass. Ten per cent dextrose with a specific gravity of 1.039 is a satisfactory substance for this purpose. A technic for obtaining anesthesia suitable for upper abdominal surgery employing these principles has been devised.[1] The desired dose of pontocaine (10 to 20 mg.) is made up to a 1 per cent solution in isotonic solution of sodium chloride. To this is added 1.5 parts of 10 per cent dextrose. The specific gravity of this mixture is now 1.027. This mixture is injected slowly (0.25 cc. per second) in the third lumbar interspace with the patient on the side. Prior to starting the injection, the table is turned in

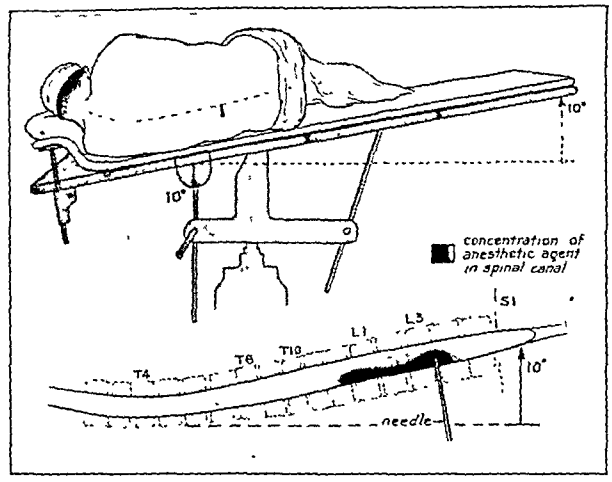

Fig. 8.—Position of patient for injection of anesthetic agent, with diagram illustrating the distribution of the agent in the spinal canal during and immediately following the injection, when hyperbaric gravity technic is employed.

the head down position, 10 degrees from the horizontal, with the patient's head elevated to raise the cervical and upper thoracic spine. The patient immediately is turned on the back, and the height of anesthesia should be tested almost constantly until the desired level is obtained. The level of anesthesia usually will be to the nipple line (fourth thoracic segment) in one to two minutes. The patient should not be left in the head down position longer than one minute unless tests show the anesthetic level to be lower than the xiphoid process (sixth thoracic segment). An accurate determi-

nation of the height of anesthesia should be repeatedly obtained as long as the table is in the head down position and for several minutes thereafter. Figures 8 and 9 represent attempts to demonstrate graphically the course of a hyperbaric (heavier than spinal fluid) anesthetic solution in the spinal canal when the gravity technic is employed.

Figure 10 represents diagrammatically the distribution of a spinal anesthetic agent in greatest concentration in the upper and midthoracic segments, with corresponding areas of intensity of surface anesthesia.

This technic can be varied for lower levels of anesthesia by changing the tilt of the table or the length of time it is left in the head down position.

When spinal anesthesia is used for upper abdominal surgery the dangers of serious impairment of respiration must be kept in mind. It is of utmost importance that respiratory impairment should be recognized immediately. This, of course, calls for the attendance of one familiar with these dangers and equipped to institute immediate treatment. If the agent is distributed as far cephalad as the fourth thoracic segment, the intercostal muscles below this level usually will be inactive and the elevation of the ribs and expansion of the chest on inspiration will be due to the pull of the upper intercostal muscles. If the agent continues to progress upward, the remaining intercostal muscles become inactive and the chest no longer expands with inspiration. If the patient is asked to take a deep breath at this time, only diaphragmatic breathing can be observed. The chest remains entirely motionless or may even retract on inspiration. This is one of the earliest and most important warning signs that the anesthesia is going too high. At this time or soon afterward the patient may complain of numbness or tingling in the hands. This is, of course, due to involvement of the roots of the brachial plexus (fig. 6). Figure 11 illustrates the normal position assumed by the chest and abdomen on inspiration, as well as their position after complete intercostal paralysis. If the fourth cervical nerve is involved, the diaphragm becomes paralyzed with complete respiratory arrest. Before the phrenic nerves are completely involved, the conscious patient attempts to increase the size of the chest cavity by using the accessory muscles of respiration. This can be detected readily by observing the patient's neck for increased activity of the sternomastoid and platysma muscles. The patient may also lose the voice and become apprehensive. If

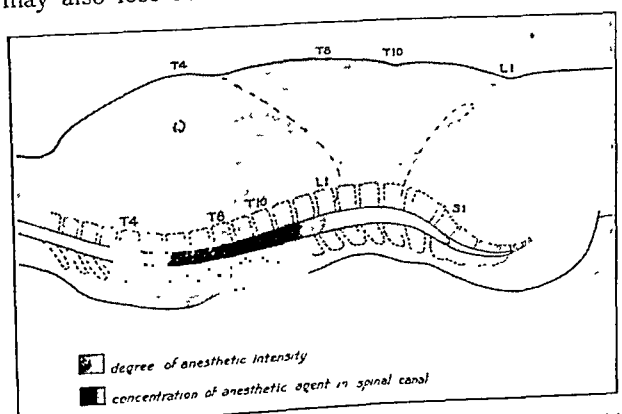

Fig. 10.—Distribution of the anesthetic agent in the spinal canal with corresponding areas of anesthesia intensity after anesthesia has been established, when hyperbaric gravity technic is employed.

unrelieved, this condition may lead to hypoxia, circulatory collapse and death. The treatment is obvious. It consists in the administration of oxygen with some mechanical assistance to inspiration if there is inadequate respiratory exchange. This assistance is absolutely essential if there is complete respiratory arrest. The assistance to respiration can best be accomplished by administering oxygen from a gas machine and exerting rhythmic pressure on the rubber breathing bag coincidental with each attempt at inspiration or about sixteen times per minute. Obviously the establishment of a free and unobstructed airway is imperative. Respiratory stimulants are not indicated and neither

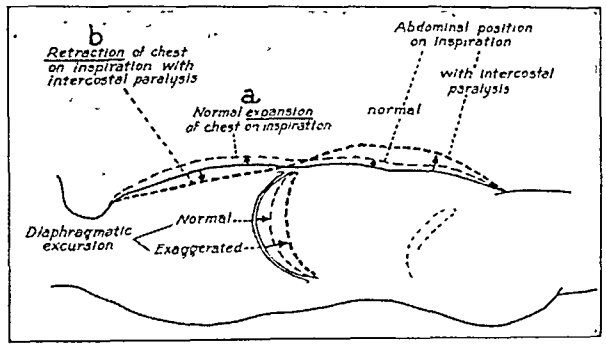

Fig. 11.—Position assumed by chest and abdomen with (*a*) normal inspiration and (*b*) inspiration after complete intercostal paralysis. Note exaggerated diaphragmatic and abdominal motion.

are pressor drugs unless circulatory depression occurs. If immediate and adequate treatment is instituted, this condition need cause no great alarm, and usually secondary circulatory depression does not occur. Furthermore, the surgical procedure need not be delayed. The period of respiratory depression rarely lasts longer than twenty to thirty minutes.

Many theories have been advanced to explain the fall in blood pressure which so frequently accompanies spinal anesthesia. Whether the cause of the blood pressure fall is blocking of the nerves to the adrenal glands, direct action of the anesthetic agent on the nerve centers of the medulla, absorption of the agent into the blood stream, venous stagnation or blocking of the vasoconstrictor fibers in the anterior spinal nerve roots, we are faced with the fact that a rather pronounced fall in blood pressure frequently is observed during spinal anesthesia. Falls in blood pressure are much more frequent with high spinal anesthesia than when the anesthesia is confined to the lower part of the abdomen. This hypotension may be alarming and should always be considered unphysiologic. Surgical manipulation in the abdomen, of course, plays a part in the production of blood pressure fall, and severe circulatory depression always follows unrelieved respiratory depression. While a severe blood pressure fall often is not observed with high spinal anesthesia, one should always remember that such an occurrence may be manifested independent of the operative procedure and without any demonstrable respiratory depression. The routine use of 50 to 75 mg. of ephedrine intramuscularly a few minutes prior to the induction of spinal anesthesia is a valuable safeguard against circulatory depression. Many of the pressor drugs have been employed successfully to combat blood pressure falls which in spite of prophylactic ephedrine have reached a level low enough to require treatment. Epinephrine and neosynephrine are effective in raising blood pressure; however, these drugs often have a rather transient effect and may disturb cardiac rhythm. Intramuscular ephedrine alone is usually effective but is somewhat slow in action. An extract of the posterior part of the pituitary gland (pitressin) is an effective blood pressure raising drug and is usually prompt in action. The fact that this drug may constrict the coronary

arteries and decrease the blood supply to the heart must be borne in mind. This danger may be minimized if it is combined with ephedrine. A combination of 5 units of pitressin and 25 mg. of ephedrine intramuscularly has proved very satisfactory in the treatment of blood pressure falls due to spinal anesthesia.[2] The response is usually prompt and well sustained, and one dose as a rule is sufficient. One fourth to one third of this dose can be given intravenously in the presence of a severe fall in pressure. The heart rate and rhythm usually are changed but little if any with this combination.

Nausea, retching and vomiting are frequent annoying complications of spinal anesthesia. No single factor is responsible for this complication, and probably more than one factor plays a part. The presence of the anesthetic agent in sufficient quantity in the fourth ventricle in dogs will produce vomiting. This may be the cause of vomiting under spinal anesthesia in some instances. Reduced blood pressure with tissue hypoxia, direct action of the drug on centers in the fourth ventricle through the circulation, traction reflexes in the abdomen and side effects of preoperative narcotics may all be factors contributing to nausea and vomiting under spinal anesthesia. If this complication is more than a momentary disturbance, the patient should be rendered unconscious by the use of an inhalation agent such as cyclopropane or nitrous oxide or by the intravenous administration of an anesthetic agent such as pentothal sodium. This enables the surgical procedure to proceed uninterrupted and relieves the patient from an uncomfortable and disturbing experience. The danger of vomitus being aspirated into the trachea should always be borne in mind when a general anesthetic is administered for the relief of nausea and vomiting.

Sometimes patients object to being awake during an operation, although not nearly as often as is generally thought. An additional dose of morphine intravenously after the patient is in the operating room prior to

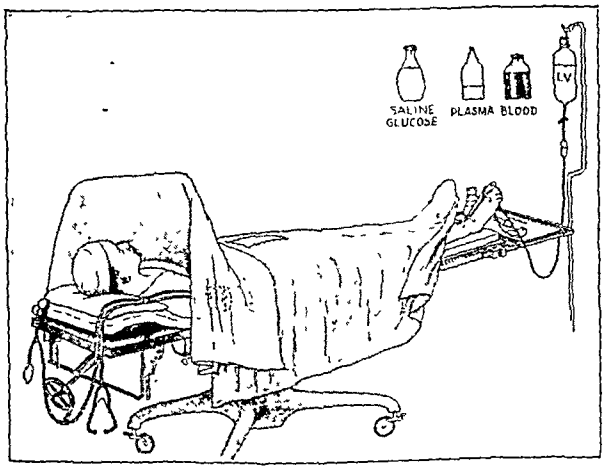

Fig. 12.—Patient ready for operation under spinal anesthesia. Note blood pressure cuff and constant intravenous drip in place (needle in saphenous vein). Supportive fluids and supplementary intravenous agents available.

induction of spinal anesthesia often allays apprehension and nervousness. There is no reason why any patient who objects to being awake during an operation cannot have the comfort of being asleep and at the same time not be denied the advantages of spinal anesthesia. The administration of cyclopropane in concentrations only high enough to maintain unconsciousness is a valuable adjunct to spinal anesthesia. If for any reason the administration of an inhalation anesthetic is undesirable, the patient can be rendered unconscious by the

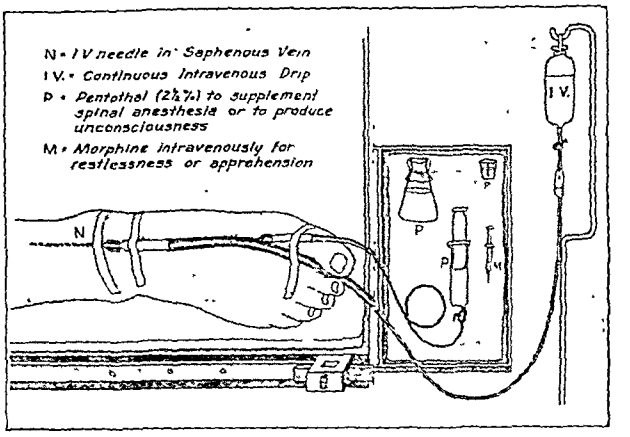

Fig. 13.—Details of intravenous drip and supplementary intravenous agents.

use of an intravenous barbiturate such as pentothal sodium. The placing of an intravenous needle in one of the great saphenous veins near the medial malleolus and maintaining a slow drip of fluid through the needle throughout the entire operative procedure permits the rapid administration of supportive fluids such as glucose, blood and plasma or the administration of an intravenous anesthetic agent (fig. 12).

With the use of a technic which distributes the major portion of the anesthetic solution in the spinal canal at the level from which the nerves supplying the upper part of the abdomen arise, the need for supplementary anesthesia because of insufficient duration becomes less frequent. However, if it becomes obvious that the operation is going to outlast the anesthesia, a supplementary anesthetic must be employed. Pentothal sodium is an excellent intermediary agent facilitating the transition from spinal to inhalation anesthesia. This transition can usually be made without any disturbance of the operative field, provided the supplementary agents are started before the patient begins to feel pain or there is any loss of muscular relaxation.

With the increasing use of continuous spinal anesthesia,[3] the need for supplementary anesthesia for longer surgical procedures is disappearing. This technic is valuable and has made spinal anesthesia practical for a large group of patients for whom it was frequently unsatisfactory or inadequate.

With the use of proper agents and methods and with an appreciation of some of the physical and physiologic factors involved in the production of adequate spinal anesthesia, the distribution of the agent in the spinal canal can be fairly accurately controlled. If this control of the anesthesia is combined with the judicious use of supportive measures and supplementary agents, there are few patients to whom spinal anesthesia need be denied for surgery in any part of the abdomen.

The prime contraindication to spinal anesthesia is still the absence of a spinal anesthetist.

THE USE OF CONTINUOUS SPINAL ANESTHESIA

UTILIZING THE URETERAL CATHETER TECHNIC

MAJOR EDWARD B. TUOHY
Chief of Anesthesia and Operative Section, Percy Jones General Hospital, Battle Creek, Mich.
MEDICAL CORPS, ARMY OF THE UNITED STATES

In a previous communication [1] the methods and indications for continuous spinal anesthesia were described and the fundamental premises of a method (malleable needle technic) originally suggested by Lemmon [2] emphasized. At this time there should be little doubt that the fractional or serial administration of spinal anesthetic agents is safer relatively than single large dose administration—so-called "single shot spinal." However, in certain instances it is not always practical to utilize continuous spinal anesthesia because one is administering a small initial dose of the spinal anesthetic and one does not contemplate or desire to inject any more of the anesthetic; for example, for hemorrhoidectomy or transurethral prostatic resection. Thus, certain surgical procedures do not lend themselves as practical for utilizing continuous spinal anesthesia regardless of the technic employed.

The continuous spinal method is indicated usually and advantageously in such surgical operations as bilateral primary inguinal herniorrhaphy, operations for recurrent hernias (inguinal or ventral), certain abdominal laparotomies in which the surgical risk is good, such as operations on the biliary tract or stomach, lengthy orthopedic procedures on the hips or lower extremities and neurorrhaphies of the sciatic nerve. At this juncture it should be stated again that debility and cachexia and impending surgical shock should deter one from the use of a spinal anesthesia by any method. I believe that there are few if any exceptions in these situations.

The chief difficulties which I have experienced coincidental with the Lemmon technic [2] have resulted from the dislodging of the malleable needle from the subarachnoid space, thus invalidating the effectiveness of the procedure. It is true that on occasion it has been difficult to introduce the malleable needle satisfactorily into the subarachnoid space, but this objection is relatively negligible. Breakage of the needle is a remote but actual hazard to be conjured with continually. In an effort to obviate the difficulty of the malleable needle becoming displaced, a new method of performing continuous spinal anesthesia was devised utilizing a ureteral catheter. Previous reports of the use of a ureteral catheter for caudal anesthesia [3] and for continuous subarachnoid drainage for meningitis as advocated by Love [4] prompted the trial of a ureteral catheter for the purpose of continuous spinal anesthesia. It was my feeling that a number 4 ureteral catheter would be less traumatic to tissues than a needle (malleable) when it is left in position for the duration of an operation, and if the catheter was satisfactorily introduced into the subarachnoid space it would not become dislodged as easily as a needle. The hazard of breakage of the catheter during any portion of the procedure did not appear to be as great as that with a needle, because of the flexibility and mobility of the catheter; nevertheless this complication is potentially a possibility.

TECHNIC

The introduction of the ureteral catheter (x-ray type, leaded with a round tip) number 4 is accomplished by the following method: The patient is placed on the table in the lateral recumbent position, usually on the patient's right side, shoulders and hips perpendicular to the table and close to the edge, the thighs flexed on the abdomen so that the patient's knees and chin are close together. The skin is surgically prepared and sterile drapes are placed about the site of the injection. The space between the third and fourth or fourth and fifth lumbar vertebrae is used for the site of injection. Occasionally the space between the second and third lumbar vertebrae is utilized if the lower lumbar interspaces appear to be rather narrow. The skin and subcutaneous tissues at the site of the injection are anesthetized then with 1 per cent solution of procaine hydrochloride. In most instances 25 to 50 mg. of ephedrine sulfate is injected intramuscularly at the site of injection prior to the administration of the spinal anesthetic. In order to facilitate the introduction of the 15 gage needle which is to guide the ureteral catheter, the skin at the site of the puncture is broken by means of a skin awl. Following this the 15 gage needle, 3 to 3½ inches (7 to 9 cm.) in length, with a flush fitting stylet, is inserted into the subarachnoid space. A definite "snap" is felt when the needle penetrates the ligamentum flavum and thence the dura and arachnoid tissue. On completion of a successful puncture of the arachnoid the stylet is removed and a 20 cc. luer syringe containing 400 mg. of procaine or metycaine hydrochloride (4 cc. of a 10 per cent solution) is attached to the hub of the needle and the anesthetic agent is diluted with spinal fluid up to a total volume of 12 to 15 cc. The resultant mixture is a 3⅓ or 2⅔ per cent solution. The concentration of the solution can be varied at will by altering the amount of spinal fluid withdrawn. Solutions of less than 2 per cent or over 4 per cent concentration seldom are necessary. The more dilute solutions, for example, 2 to 2.5 per cent, are used usually for operations in the upper part of the abdomen because they will allow the injection of a greater volume of solution without increasing the initial total dose, and thus segmental dermatome anesthesia will be produced sufficiently high. The syringe is removed from the needle hub and the ureteral catheter is inserted through the needle into the subarachnoid space. Centimeter markings on the catheter are used to measure with so that one can determine how far to introduce the catheter. The tip of the catheter is advanced about 4 to 5 cm. beyond the end of the point of the needle into the subarachnoid space. This is sufficiently far to prevent the catheter from slipping out of place. The 15 gage needle is removed from the intervertebral space and slid off the free end of the catheter. A 22 gage needle ½ inch (1.27 cm.) in length is inserted into the free end of the catheter and to this needle hub is attached a one way stopcock adaptor. One end of this adaptor fits the hub of the 22 gage needle and the other the syringe containing the

anesthetic solution. Originally I did not use a one way adaptor, but without it I have had several cases in which the spinal fluid pressure was sufficient to force the plunger back into the syringe and consequently alter the concentration of the solution; so I have added the one way adaptor and obviated this difficulty. Preparations for injecting the spinal anesthetic via the catheter now are complete. As the bore of the number 4 ureteral catheter is so small, little solution is needed to fill its lumen, and it is not necessary to allow for the minute loss of solution in calculating dosage of the anesthetic agent. Initial doses will vary between 80 and 120 mg. In general the original fractional dose should be a fourth or fifth less than the dose contemplated for a single injection type of anesthesia.

When the initial dose has been injected the patient is turned carefully onto his back and the catheter is brought out to his side and fastened in place to the operative mattress with adhesive plaster. Additional quantities of the anesthetic agent should be injected at the first indication that the patient is having pain or that there is a lack of muscular relaxation. Usually within thirty-five to forty minutes it is necessary to add additional amounts (2 cc., or 52-66 mg.) of the anesthetic agent. Subsequent doses are added in the same manner as they are required.

At the completion of the operation, before an attempt is made to remove the catheter, the patient is turned on his side again and if possible the thighs and head are flexed and then the catheter is withdrawn gently from the subarachnoid space. The purpose of flexing the patient is to relieve any tendency for the interspinous ligaments and spinous processes of the vertebrae to impinge on the catheter.

COMPLICATIONS

There has been no increase in the incidence of spinal puncture headache as compared with single dose spinal anesthesia or routine spinal puncture. There have been no instances of persistent paresthesia in the limited number of cases so far (250). Bleeding from the soft tissues at the site of injection is encountered occasionally, but only if difficulty has been experienced in making the lumbar puncture. Failure to introduce the catheter successfully has occurred in 2 cases. No instances of bladder or rectal dysfunction have been noted. There has been no evidence so far of any infection in the subarachnoid space or in the soft tissue.

COMMENT

At present the catheter technic, as compared with the use of the malleable needle, has been attended by fewer mechanical difficulties in my experience. There have been no situations in which the catheter has inadvertently slipped out of the subarachnoid space. It has been my opinion that the catheter causes less trauma to the soft tissues than does a needle over a protracted period of time.

The failure to insert the ureteral catheter easily in some cases has been found to be due to the fact that the 15 gage needle was advanced too far intrathecally and insufficient space was remaining between the point of the needle and the body of the vertebrae to allow the catheter to pass. If the needle is withdrawn slightly, with an effort meanwhile to advance the catheter, entrance of the catheter into the subarachnoid space will be accomplished. One precaution must be exercised; namely, that the catheter should not be withdrawn through the needle once the catheter has entered the subarachnoid space, because the sharp point and bevel of the needle may shear off the catheter. If the catheter must be removed or partially withdrawn for any reason during the procedure, the needle should be withdrawn first from the lumbar interspace. The direction (cephalad or caudad) which the catheter will advance in the subarachnoid space after the tip of the catheter leaves the end of the guiding needle cannot be predicted positively; however, if the round tip of the catheter is bent slightly before it is introduced into the lumen of the needle, I have found that the catheter will advance cephalad in most cases. This has been verified radiographically by using the leaded ureteral catheters. In the event that the catheter turns caudad on entering the subarachnoid space, this fact can usually be detected shortly after the initial dose of the spinal anesthetic has been introduced because of the segmental distribution of the resulting anesthesia. When this situation occurs it is suggested that the remaining amount of the anesthetic solution in the syringe be diluted with an equal volume of isotonic solution of sodium chloride, and twice as much solution (volume) should be administered in order to produce higher dermatome anesthesia. Barbotage is not recommended, but it can be accomplished via the catheter if it is deemed necessary.

This procedure (ureteral catheter technic) has been taught to student officers in training in anesthesiology and I think the technic cannot be too difficult, as they can successfully use the equipment without perceptible difficulty in a relatively short time. I know that some other anesthetists are using this method, and it appears to be satisfactory also in their experience. The challenge that the 15 gage needle is unnecessarily traumatic for subarachnoid puncture is accepted, but in retaliation I offer the data that up to the present time no untoward effects have resulted from the use of this 15 gage needle, and it has been just as easy to insert this needle as it has been the malleable needle used with the Lemmon procedure. It has appeared to me that the efficient operation of the catheter system is an improvement in achieving the fundamental principles of continuous spinal anesthesia as originally suggested by Lemmon. Naturally it will be necessary to have further experience with a larger series of cases to have a complete evaluation of this method, but I think that it is worthy of trial and is to be recommended as an adjunct to this type of anesthesia. The total cost of this equipment is relatively small as compared with the equipment necessary with other methods of continuous spinal anesthesia. This may or may not be an important factor.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. EVERSOLE AND TUOHY

DR. WILLIAM T. LEMMON, Philadelphia: With an experience of over 15,000 cases and with the record of low mortality, it is hard to have much to say except in complement of the work done by Dr. Eversole. He hit the keynote when he said it is not the drug, it is not the method, but the trained man who is giving the anesthesia. I would rather have a trained anesthetist anesthetize me or my patients than to have a much superior method with an absence of training and experience. When this method is used by others of lesser training and experience it produces death—rapid, sudden and dramatic death. I know that, because I was selected to be on the Anesthesia Study Commission of the Philadelphia County Society with

Dr. Ruth, and we have the cases and the records. The trouble is not with the method, it is not with the drug, but it is either with the patient or with the individual handling the method and administering the drug. Every method that was instituted to help the patient was always instituted too late, and the means of getting out of difficulties were usually injection of epinephrine into the heart, which from our experience should never be used, because every one of those patients died. I know in the hospitals around Philadelphia County that we have the anesthetists on the alert. They know that if anything happens we are going to have not only a hospital investigation but a study of that case, and we want to find out where the fault is. The contraindications to spinal anesthesia are practically nil, but the contraindications to surgery plus spinal anesthesia are many. You cannot improperly prepare a patient for surgery and expect him to take surgery and anesthesia. If a patient is prepared for surgery he will take the handicap of the anesthesia in his stride, so to speak. Anything that is a contraindication must be eliminated before the doctor operates on his patient. I want to compliment Major Tuohy on his ingenious idea and method of using the ureteral catheter in the production of continuous spinal anesthesia, because if its disadvantages are outweighed he has a definite advantage in that his catheter will not become displaced. That, in the hands of the inexperienced, is one of the big troubles.

DR. URBAN H. EVERSOLE, Boston: Dr. Lemmon stressed an important point when he spoke of the dangers of this technic. I assume he meant the dangers of this particular technic in contradistinction to the inherent dangers of all types of spinal anesthesia. I accept that criticism. In my opinion, in the virtue of the technic lies its danger. There is a wide margin between the specific gravity of the solution injected and the specific gravity of spinal fluid. This enables the anesthetic agent to run cephalad rapidly. With this rapid cephalad progression there is the danger that it will go too high, and respiratory paralysis will ensue. As to the question concerning the administration of dextrose into the spinal canal, I am sure that 10 per cent dextrose can be satisfactorily sterilized without chemical change. I do not hesitate to put sterilized 10 per cent dextrose into the spinal canal after having done it in nearly 20,000 cases.

MAJOR E. B. TUOHY, M. C., A. U. S.: With regard to the question which Dr. Romberger brought up concerning the sterilization of the catheters, I agree full well with him, and I feel more safe myself if the catheters are autoclaved under high pressure. This is by far the best technic. However, the catheters do not stand the sterilization quite as well by this means. The lacquer which is on the outside of the catheters will break down a little more rapidly on protracted and repeated sterilization. In my experience so far I have been able to use the catheters for ten or twelve separate cases. This implies, of course, that there is careful scrutiny of the continuity of the catheters and the way in which they are handled. Concerning the indications of whether or not spinal anesthesia will be used for the type of cases which Dr. Romberger mentioned, I have no bone to pick on that score. One has to be a little cautious in what is written in the literature with regard to spinal anesthesia when you say that this method may be used for such and such a type of case. I have had no experience in the use of epinephrine or similar vasoconstrictor substances in conjunction with the subarachnoid injection of anesthetic agents.

Hospital Facilities in Japan.—Hospital facilities in Japan are not sufficient to meet the needs of the people (19 beds per 10,000 people, as compared to the average for the entire United States of 97 beds per 10,000 people). . . . The greatest number of hospital beds (about three fifths) is found in the larger cities, whereas the rural areas have only small dispensaries. The larger hospitals, connected with the medical schools, compare favorably both in reputation and in equipment with teaching hospitals in Europe; but in the smaller cities and towns hospitals are little more-than rest homes.—Simmons, James. S., and others: Global Epidemiology, Philadelphia, J. P. Lippincott Company, 1944.

INTERNSHIPS AND RESIDENCY TYPE TRAINING IN UNITED STATES NAVAL HOSPITALS

VICE ADMIRAL ROSS T. McINTIRE (MC)
Surgeon General, United States Navy
WASHINGTON, D. C.

The Medical Corps of the Navy has been interested for a long time in the development and fullest possible utilization of the notable facilities it possesses for graduate educational training of its medical officers. The United States Naval Hospitals on this continent are as fine as any hospitals in the world; many of the United States Naval Dispensaries are actually small hospitals staffed, equipped and conducted along lines comparable to the best of civilian hospitals of similar size; and some of our fleet hospitals and others in outlying areas even near to combat zones are so conducted that all of these activities and facilities provide outstanding training opportunities for young doctors.

This interest in the development of an educational program was not solely for the benefit of the medical officers assigned to these activities but primarily and fundamentally because we are concerned with everything which counts for improvement and betterment in standards of medical care of our patients. It has been entirely incidental, therefore, that better than average opportunities for internship and residency type training are thus provided for our medical officers. As a morale builder nothing could be more important than that these men may receive substantial training while on active duty, thus increasing their medical stature and affording them opportunities to make better doctors of themselves.

INTERNSHIPS

General rotating internships in naval hospitals were established in 1924. At the present time thirty-eight naval hospitals have been approved by the Council on Medical Education and Hospitals of the American Medical Association for internship training on the same standards as those of civilian hospitals.

Under the accelerated program these naval internships consist of a nine months rotating service, providing all interns with three months on each of the three groups of services according to the following general schedule:

1. Medicine, neuropsychiatry and clinical laboratory.
2. Surgery, urology, ophthalmology, otolaryngology and roentgenology.
3. Obstetrics, pediatrics and gynecology.

These internships are acceptable for credit before state boards of licensure to the same extent as similar internships in civilian hospitals.

In order to maintain approved standards for internships certain essentials are necessary. Following a recent review of the internship training program in naval hospitals by the Board of Honorary Consultants to the Surgeon General of the Navy, the general standards governing internship training in naval hospitals are those outlined by the Council on Medical Education and Hospitals of the American Medical Association [1] for civilian institutions as adapted to naval needs.

1. Essentials of an Approved Internship, J. A. M. A. 118:1497 (April 25) 1942.

RESIDENCY TYPE GRADUATE TRAINING

United States Naval Hospitals in general are organized and staffed along departmental lines in the specialties with standards of practice in these institutions so complete and so competently conducted that the training received by naval medical officers assigned to duty in these activities has long been recognized as the equal of any formal residency in the better teaching and other civilian hospitals. However, these activities had never sought to be formally surveyed and listed as providing residency training according to civilian standards by such organizations as the Council on Medical Education and Hospitals of the American Medical Association and the American College of Surgeons until the middle of last year, when it was determined that such formal recognition would be advantageous to all concerned. One of the important functions undertaken by the newly established Professional Division of the Bureau of Medicine and Surgery of the Navy Department immediately on its inception in 1944 was that of a formal graduate educational program. This included a review of these opportunities for graduate training in medicine and its specialties, and the making certain that all of our naval hospitals would have adequate libraries, staff and departmental conferences, bedside instruction and other essentials to such training along conventional lines.

From the beginning of mobilization many noted medical teachers and specialists had come into service as reserve officers; many younger men in the midst of their residencies in various of the specialties left these to be commissioned in the Navy; many of our regular naval medical officers had been given special courses of varying lengths; and we still have innumerable young medical officers coming to us direct from civilian hospital internships or even fresh from medical schools to intern in our naval hospitals. Consequently we have had the necessary elements for outstanding teaching and instruction with younger men whose careers were otherwise being interrupted and still younger recently graduated officers, eager for opportunities to train and develop themselves. Not all of the latter want to be specialists, nor do we want them to be, but we do wish to make of them the best possible type of doctors primarily and fundamentally, as mentioned before, for the benefit of our sick and wounded, and incidentally for their own benefit.

Any straight service in a single department or through a group of allied specialties, following one year of rotating internship, is classed as a residency. The Council, the American boards certifying in the specialties, the American College of Physicians and the American College of Surgeons are concerned with this subject of residency type graduate training. The Council and the American boards, acting jointly, review and survey facilities for this work in all the specialties; the American College of Surgeons similarly surveys for formal approval of residencies in surgery and the surgical specialties. Lists are published annually by the American Medical Association and the American College of Surgeons carrying the names and locations of hospitals, civilian and others, granted such official approval and recognition. Certain essentials of graduate education in the specialties are required to obtain such approval and listing and these are outlined in detail by both of these organizations.[2] Outstanding among these requirements are adequate library facilities and staff conferences, as well as bedside clinical instruction.

Lists of current periodicals and books considered minimum for an acceptable library are supplied each naval hospital through the Bureau of Medicine and Surgery based on the recommendations of the aforementioned organizations concerned with graduate medical education. The minimum requirements for a good library are thus established by this bureau, and this minimum will be found uniform in all naval hospitals. It is obvious that these libraries will be further augmented by certain additional journals and many other books, especially in hospitals designated for the care of certain special types of diseases or illnesses. Nursing and dental publications are included.

It is directed also that staff conferences include, as a minimum, one departmental staff meeting weekly (interdepartmental conferences may be arranged between related departments) and a general staff meeting at least twice monthly. Clinicopathologic conferences and literature reviews ("Journal Club meetings") at regular intervals may be incorporated as part of either program. In larger activities the latter conferences are preferable in the departmental meetings, while in the smaller activities they may become part of the regular general staff conferences or may be separate from them but including all departments as an additional general conference.

All activities providing residency type training in the specialties must make annual reports in triplicate to the Bureau of Medicine and Surgery of the Navy covering periods of assignment of junior medical officers to such services, so that credit for the time spent may be recorded in the biographic files of (*a*) the American Medical Association, (*b*) the American College of Surgeons (in the surgical specialties) and (*c*) the Bureau of Medicine and Surgery.

Junior medical officers assigned to specialty services in naval hospitals will not be termed residents, nor will such services be designated formally as residencies. However, periods of service in activities approved officially for residency type training are given credit before the American boards and others. Services in unapproved activities are recorded as unclassified, but the officer may be able in many such instances to obtain official American board or other recognition for time spent in assignment to such services. Cumulative credit is obtainable for interrupted periods of service during wartime. Less than six months in any service will usually require individual consideration for credit.

Officers asking credit for eventual certification by one of the American boards have been advised to write to the secretary of the board concerned requesting a copy of the "Record of Professional Assignments" which is kept by him as a log of his activities. The latter are attested by his commanding officers for later use whether his service assignments in a given specialty have all been in officially approved activities or in facilities such as naval dispensaries not so listed but nevertheless providing outstanding experience under qualified supervision.

For the present, only naval hospitals have been directed by this bureau to make formal application for official approval of residency type training. Medical officers in command of other smaller naval facilities where opportunities exist for outstanding graduate training in any of the specialties may make arrangements for similar application through the bureau whenever in the opinion of the commanding officer this is

[2] Essentials of Approved Residencies and Fellowships, J. A. M. A. 113: 794 (Aug. 26) 1939. Minimum Standard for Graduate Training in Surgery, Bull. Am. Coll. Surgeons 29: 432 (Dec.) 1944.

justified. Medical officers serving in naval dispensaries, hospitalizing certain of their patients in affiliated civilian institutions, such as in departments of obstetrics and gynecology, otolaryngology or pediatrics, will receive official board and other credit if these affiliated hospitals are already approved by the Council and the colleges.

WARTIME AND PEACETIME OPPORTUNITIES FOR GRADUATE TRAINING

It is clearly recognized and frankly stated that many naval officers will have little or no opportunity for such training during wartime because of the tremendous pressure and need for medical officers on our ships and in our outlying stations. It is a fact, nevertheless, that many others do have such opportunities while actually performing their military duty if fortunate enough to obtain such assignments as these that have been described. Several notable policies have been consistently followed, as far as this was possible under the circumstances of wartime stress.

A constant effort has been made by the Personnel Division of the Bureau of Medicine and Surgery to assign men with outstanding training in a specialty to service in that specialty where he is obviously most proficient. This policy extends downward through the ranks of those with lesser degrees of proficiency or only partial training.

All naval officers, except those classified for limited duty, are expected to have a period of sea duty fairly soon after their induction into service. On nearing the completion of this they are encouraged to express preference for future assignments nearer home. It is logical that these assignments should be consistent so far as possible with the previous experience and proficiency of the man concerned.

It is true that the assignment of an officer already partially trained in a civilian residency may have to be changed before his full training, according to American board or college requirements, can be completed by us. Credit for this time spent will nevertheless be his and in the meantime that naval hospital will have had the advantage of the partial training this young man had had. He may need to be sent out to some other type of duty, or it may become necessary to assign him to another naval hospital, but in the latter event time will accumulate to his credit. We cannot promise anything in advance about services these days, but to the extent that has been outlined these plans are logical, consistent, and to a large degree workable.

What this program of graduate educational training in naval hospitals will mean to the rehabilitation of medical officers before return to civilian practice, and what it will mean for the future of the regular naval Medical Corps, can be only incompletely estimated. One thing is certain: the establishment of such programs in our institutions will unquestionably be maintained into peacetime. Regular Navy officers of the Medical Corps now and in the future have opportunities for specialization and achievements in the medical profession quite comparable to those of civilian life, whereas heretofore such opportunities have been either limited or not fully promoted. Certification by the American boards, far greater participation in the activities of the colleges and other national organizations and recognition of attainments should follow in the future for officers of the regular Medical Corps along the same lines as those that are so common to the civilian medical profession.

Finally, let it be reemphasized that there is no greater stimulus to good medical care of patients than to incorporate a program of graduate medical education for the officers serving and caring for these patients. This truism applies to all medical officers of any hospital from the top down.

Better study of the patients, careful supervision and personal clinical instruction of younger medical officers by older teachers, departmental and staff conferences for discussion and constructive criticism, the constant use of good libraries, and other similar advancements, even now while we are in the midst of war are both possible and necessary for the basic purpose of maintaining and improving the standards of medical care given the sick in our hospitals. The educational aspects of all this are incidental, it is true, but they are there and the opportunities afforded by them are magnificent.

It will be clear from the foregoing that we intend our good records for medical care of patients in the past shall be not merely maintained but steadily improved. We have the not unwarranted feeling that Navy trained physicians will be well to the front among the leaders of the profession in the future when peace comes again.

BORIC ACID OINTMENT

A STUDY OF POSSIBLE INTOXICATION IN THE TREATMENT OF BURNS

LIEUTENANT CARL C. PFEIFFER, MC-V(S), U.S.N.R.

ENSIGN LOIS F. HALLMAN, W-V(S) (H), U.S.N.R.

AND

LIEUTENANT ISIDORE GERSH, H-V(S), U.S.N.R.

Boric acid ointment has been used for many years as an antiseptic and bland preparation for the treatment of burns. The favorable results obtained in treatment of the victims of the Cocoanut Grove disaster when boric acid ointment or white petrolatum was used under pressure dressings resulted in an official recommendation of this type of therapy by the Subcommittee on Burns of the National Research Council.[1] On the basis of these findings a circular letter was sent by the Bureau of Medicine and Surgery to all medical officers in which this form of treatment was summarized. At that time Cope[2] suggested that "too rapid absorption of boric acid might result in poisoning." Analyses of the urine of 20 of his patients showed that a maximum of 2.0 Gm. of boric acid might be excreted in the first twenty-four hours by patients with extensive burns. Later when saturated boric acid solution was used to irrigate granulating wounds as much as 2.5 Gm. was excreted in the urine in twenty-four hours. All patients maintained

normal kidney function, and these investigators concluded that prompt excretion did not lead to toxic levels of boric acid in the body.

In May 1943 Dr. A. C. Ivy suggested that in view of this recommendation further studies should be made on the toxicity of boric acid, with particular attention to the effect on bone marrow since severe anemia was one of the constant late findings in extensively burned patients. The immediate need of this study, however, was decreased by the recommendation of a joint session of the Subcommittees on Burns and Surgical Infections on July 17, 1943, in which it was recommended that boric acid ointment be discontinued in the treatment of burns. Since this official ointment has been widely used and will continue to be used by others [3] and since the studies could be prosecuted at a reduced rate along with our more urgent naval medical problems, the question of possible boric acid toxicity has been slowly but exhaustively studied at a relatively low priority level.

HISTORICAL

The literature on boron poisoning may be divided into two categories: instances of poisoning presumably due to absorption of boric acid from wounds and burns, and cases of poisoning due to oral ingestion of boron.

In 1905 Dopfer [4] first noted an intoxication which he ascribed to the application of 10 per cent boric acid ointment to a burn measuring 12 by 3 cm. in the axillary region of a 2 year old child. Eighty Gm. of ointment was applied over a period of four days. When seen by the physician on the fourth day the wound was granulating and not infected. The most evident sign of intoxication was a red rash, which had developed on the back and elbows on the second day and spread over the whole body. The patient was moribund and died in thirty minutes. Pathologic changes were not evident at autopsy. Savariaud [5] in 1914 suggested that, while boric acid solution might be harmless, wounds should never be dusted with powdered boric acid since he had seen serious intoxication develop in twelve hours in an 8 year old child whose burns of the abdomen and thighs were dusted with boric acid. Gissel [6] in 1933 reported probable poisoning of a 4 year old child whose severe burns were treated with 30 Gm. of powdered boric acid. The symptoms noted were fever, "weakening of the circulation," diarrhea, vomiting, conjunctivitis, stupor and terminal bronchopneumonia. At autopsy, four days later, lesions other than the pneumonia and degeneration of the liver and kidneys were not found. Brose [7] in 1883 reported a death following the use of powdered boric acid on a chronic leg ulcer. Best [8] in 1903 noted a similar death of an adult male when 6 ounces (170 Gm.) of powdered boric acid was used in a wound following excision of some inguinal lymph nodes. While these cases leave much to be desired as proof of boron intoxication is concerned, other cases in the literature in which the boron was given by routes in which absorption is certain leave no doubt that serious or even fatal boron intoxication can occur.

Poisoning by enemas of boric acid has been described by Sanders,[9] by Bazin,[10] by Brown and his associates,[11] after accidental injection by Peyton and Green,[12] who had a patient recover after a single subcutaneous dose of 28 Gm., and by McIntyre and Burke,[13] who had a patient recover after 15 Gm. of boric acid had been given intravenously. Owing presumably to the almost complete absorption of boric acid from solutions, by far the most insidious form of intoxication is that which occurs on irrigation of a closed cavity with saturated boric acid solution. Molodenkow, quoted by Tillmanns,[14] and more recently Ross and Conway [15] have reported deaths due to absorption of boric acid from irrigated cavities.

Numerous cases of poisoning from the accidental oral ingestion or oral therapeutic use of boric acid or borax as preservatives have been reported.[16] Poisoning has also been described in infants who have suckled from nipples cleansed with saturated boric acid solution.[17]

From the numerous case histories reported, it appears that the fatal dose of boric acid in an adult is somewhat more than 15 to 20 Gm., in an infant 5 to 6 Gm.[18] The symptoms which may be encountered in poisoning are depression of the circulation, persistent vomiting and diarrhea, followed by profound shock and coma. The temperature is usually subnormal, and most observers describe a scarlatinaform rash, which may cover the entire body. If recovery occurs, the areas affected by the rash usually desquamate and this process may extend to the mucous membranes. The clinical course may take three to five days, and death has occurred frequently four to five days after the source of poisoning was removed.

Only two groups of workers provided proof that the intoxication was due to boric acid by showing on chemical analysis that the patients had relatively large amounts of boric acid in all tissues. McNally [18] was the first to show that the highest level of boric acid occurred in the brain and the liver. Of the 6 infants whose tissues were analyzed they found an average level of 210 mg. per hundred cubic centimeters in the brain and 182 mg. per hundred cubic centimeters in the liver. These infants were accidentally fed 60 to 150 cc. of a saturated boric acid solution and died two days later. Ross and Conway [15] give an excellent account of intoxication in a 3 year old child who had continuous irrigation of the left pleural space with 5 per cent boric acid solution for empyema. Four liters per day for three days was used for this irrigation, at the end of which time the patient was in profound shock and the neck,

thorax and extremities were covered with an erythematous rash. Death occurred twenty-four hours after the irrigation had been stopped. Chemical analyses revealed 112 mg. per hundred cubic centimeters in the brain and 13.7 mg. per hundred cubic centimeters in the liver. These authors made a comprehensive summary of the literature and suggest that boric acid is much more dangerous than is generally assumed.

TABLE 1.—*Acute Toxicity of Boric Acid in Various Species By Different Routes of Administration*

Animals	Route	L. D. 50, Mg. per Kg.	Slope	Standard Error, Mg.
60 mice	Subcutaneous	2,070	4.7	± 170
40 mice *	Subcutaneous	1,740	8.0	± 130
40 mice	Intravenous	1,780	8.9	± 121
30 mice	Oral	3,450	14.0	± 158
40 rats	Intravenous	1,330	6.3	± 112
45 rats	Oral	2,660	7.7	± 220
45 guinea pigs	Subcutaneous	1,200	7.3	± 80

* Solution adjusted to p_H 7.4 with sodium hydroxide.

Since the very early (1904) studies by Wiley [19] on borax and boric acid as food preservatives but little additional pharmacologic work has been done to evaluate boric acid as a toxic agent. The unusual distribution of boron in the body, where, in contrast to other poisons, most is found in the brain, should have stimulated additional studies. Certainly, greater knowledge regarding the acute and chronic toxicity of boric acid, including its absorption from wounds, excretion and studies on histopathology, are needed before its possible toxic effect can be properly evaluated.

METHODS

Boric Acid.—Boric acid was determined on aliquot samples of tissue or urine after ashing by direct titration in the presence of glycerol.[20] In a series of 32 urines to which were added varying known amounts of boric acid, the mean recovery on analysis was 89 per cent. Spectrographic analysis for the boron lines in brain and liver fractions was done on an ARL-Deitert grating spectrograph.

Direct titration in the presence of glycerol, without preliminary ashing or hydrolysis, was employed in 1 instance to determine whether the boric acid was free or combined.

TABLE 2.—*Urinary Excretion of Boric Acid After Single Toxic Doses Given Orally*

Number of Dogs	Dosage Level, Gm. per Kg.	Mean Percentage of Boric Acid Excreted in Urine		
		Day 1	Day 2	Day 3
6	2.0	45	12	—
4	1.5	45	4	—
1	0.4	53	9	2
2	0.2	51	3	1

Phosphorus.—Urinary inorganic phosphorus was determined by the method of Youngburg,[21] using a Klett-Summerson colorimeter. Serum inorganic phosphorus and lipid phosphorus were also determined by Youngburg's technic.

Phospholipids.—The phospholipids of the brain and liver were separated by Folch's procedure [22] and the various fractions examined spectrographically for boron and phosphorus lines.

Pathology.—For histopathologic studies the animals were killed by a lethal dose of pentobarbital sodium injected intravenously. Mouse, rat and dog material was fixed in most cases by perfusion with neutral solution of formaldehyde U. S. P. diluted 1:10. A few tissues were preserved by immersion of thin slices. Tissues were embedded in celloidin. Sections of the central nervous system were stained with toluidine blue; other organs were stained with hematoxylin and eosin.

EXPERIMENTAL RESULTS

Acute Toxicity.—(*a*) Determination of L. D. 50: The acute toxicity was determined in rats, mice, guinea pigs and dogs. With regard to the first three species the data were in sufficient numbers for a statistical analysis and the acute toxicity was expressed as the L. D. 50. Forty or more animals were used in each determination. The standard error was calculated according to the method of Litchfield and Fertig.[23] Neutralized boric acid (p_H 7.4) was slightly more toxic than the unneutralized boric acid. The L. D. 50 varies from 1.2 to 3.45 Gm. per kilogram (table 1). Intravenous administration (at a rate of 2 cc. of a 5 per cent solution per minute) was the most toxic. The guinea pig was the most susceptible animal used. The prelethal symptoms in these animals were depression and ataxia (occasionally convulsions), fall in body temperature, violet-red color of the skin and mucous membranes and, in the case of the dog, persistent vomiting and meningismus.

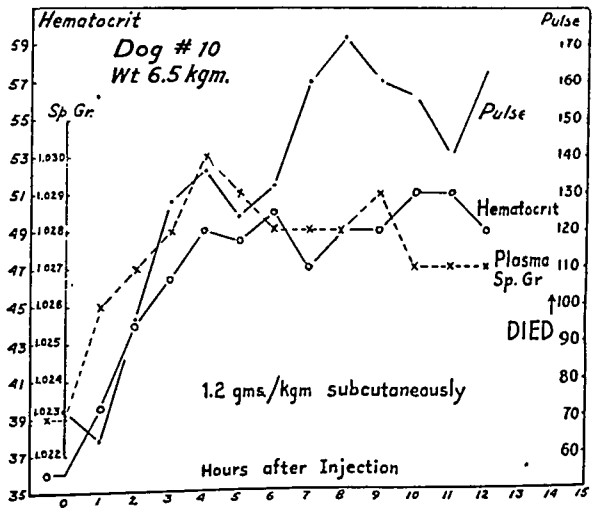

Fig. 1.—Effect of a subcutaneous dose of 1.2 Gm. per kilogram of boric acid on the hematocrit, serum specific gravity and heart rate.

(*b*) Acute Toxicity in Dogs: Dogs were given single oral doses of 2.0, 1.5, 1.0, 0.8, 0.4 and 0.2 Gm. of boric acid per kilogram. Since these doses usually induced emesis, we found that a subcutaneous injection of 30 mg. of morphine had to be given as an antiemetic before the boric acid.

Three of 6 dogs which received 2.0 Gm. per kilogram died within forty-eight hours. This is probably close to the median lethal oral dose. Two of 4 dogs died

with a subcutaneous dose of 1.0 Gm. per kilogram; hence this dosage level is probably near the median lethal dose for parenteral administration. Severe toxic symptoms were noted in 4 of 6 dogs receiving 2.0 Gm. per kilogram and in 2 receiving 1.5 Gm. per kilogram. The most obvious sign of intoxication consisted of cyanosis of all mucous membranes, with the skin becoming mottled reddish violet. The legs were rigid and the animals were unable to stand without support. Convulsions of short duration occurred in 2 animals. In 4 dogs the hematocrits, plasma specific gravity and pulse were determined hourly after subcutaneous doses of 1.0, 1.2 and 1.5 Gm. per kilogram. The changes were entirely consistent with the hypothesis that a shocklike syndrome may cause death within twenty-four hours after a single large dose (fig. 1).

Twenty-four hour urine samples were collected, and after varying intervals the tissues were analyzed for boric acid and examined grossly and microscopically for pathologic changes. Approximately 40 per cent of the dose was retained in the body for more than forty-eight hours (table 2). The mean excretion for the larger doses was 45 per cent in the first twenty-four hours and 4 to 12 per cent in the second twenty-four hour period. Thereafter only small amounts were excreted daily. From 1 dog receiving 1.5 Gm. per kilogram orally, hourly blood samples were taken for several hours. Boric acid could not be detected in either erythrocytes, leukocytes or plasma.

(*c*) Effect of Intravenous Injection on Phosphorus Excretion: Dogs operated on to produce an exstrophy of the urinary bladder were given intravenous injections of 400, 300, 250, 200, 100 and 50 mg. of boric acid per kilogram, and urine samples were collected at half hourly intervals for boric acid and phosphorus determinations. In every case there was a sharp rise in boric acid elimination, reaching a peak in one to two hours, followed by a gradual decline. After an initial inhibition lasting for one to two hours a gradual rise in phosphorus excretion occurred, which at six hours exceeded by five times the control value. This increase was most prominent at a dosage level of 250 mg. per kilogram (fig. 2). Plasma lipid and inorganic phosphorus values also were determined at hourly intervals on 3 dogs receiving 200, 100 and 50 mg. of boric acid per kilogram, but no significant changes occurred over a seven hour period.

(*d*) Effect of Acute Intoxication on Blood Electrolytes: In order to ascertain the degree of alteration which moderately toxic doses of boric acid might produce in the electrolytes of the blood stream, 2 dogs which had received 1.0 Gm. per kilogram were bled twenty-four hours after dosing and the blood was subjected to chemical analysis. With the exception of an increased nonprotein nitrogen and, perhaps, concomitant increase in serum potassium in dog 1, no significant change in the blood electrolytes was found.

(*e*) Identification of Excreted Compounds: In an attempt to determine the exact nature of the boron compound excreted, boric acid was titrated directly, without preliminary ashing or hydrolysis, in several aliquots of a single specimen of urine (965 cc.). The quantity found by direct titration accounted for 96 to 101 per cent of the boric acid found by the usual method of ashing. It was concluded that practically all of the boron in this specimen was present as unmodified boric acid. This is in accord with the findings of Wiley [19] that both boric acid and borax are excreted unchanged.

Chronic Toxicity.—(*a*) Effect of Repeated Injections on the Cellular Elements of the Blood: Because of the frequent occurrence of persistent anemia in patients with extensive burns, the possible depressant effect of boron on the hemopoietic system was considered. After control hematologic studies, 4 dogs were injected subcutaneously twice daily for forty-five days with a dose of 100 mg. of boric acid in a 5 per cent solution per kilogram. The animals were housed in metabolism cages. Hematologic studies were made twice weekly and the urinary excretion of boric acid was determined daily. Significant change in hemoglobin, erythrocytes or leukocytes did not occur during the period of observation. From the standpoint of possible cumulative toxicity it is significant that the plateau of urinary excretion was not reached until the animals had been on this dosage regimen for fourteen to eighteen days. The mean recovery when the plateau of excretion was reached amounted to 85 per cent of the amount of boric acid injected.

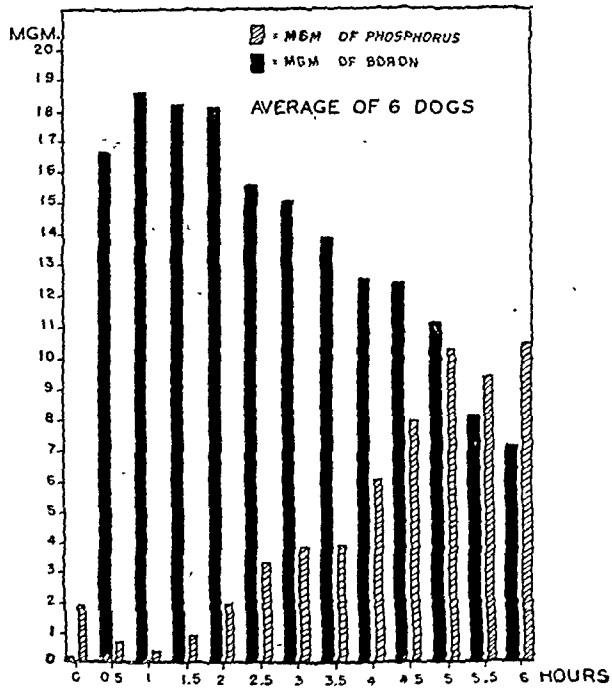

Fig. 2.—Comparative urinary phosphorus excretion after intravenous injections of 250 mg. per kilogram of boric acid.

(*b*) Effect on the Growth of Immature Rats: Five groups of 20 to 24 immature rats each were placed on a standard laboratory diet and given various levels of boric acid in their drinking water and were weighed daily to follow the rate of growth. One-tenth per cent boric acid was without effect on normal rat growth, while 0.25 per cent and all higher levels produced a definite inhibition after twenty to thirty days. The daily fluid intake was constant at 0.14 to 0.12 cc. per gram of rat daily for all three groups. At autopsy no characteristic gross or microscopic pathologic lesions were found. Complete blood counts were done weekly, but no significant change was found in the blood of these animals.

(*c*) Application of 10 per Cent Ointment to Wounds: Under pentobarbital sodium anesthesia a section of skin 13 cm. square was removed from the dorsolumbar surface of dog 204. Fifty Gm. of U. S. P. boric acid ointment was applied daily to the exposed surface and

secured with a pressure bandage. Urine was collected daily for analysis. The area of the wound was measured daily and found to decrease in size. The wound size was expressed in percentage of total surface area as determined by the formula of Benedict.[24] On the twenty-fifth day the animal was killed for autopsy and

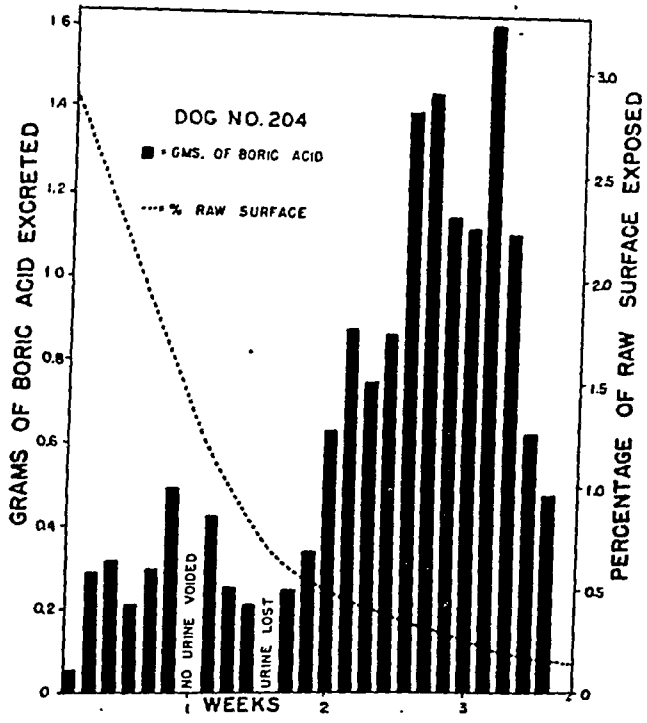

Fig. 3.—Urinary excretion of boric acid for twenty-four days when boric acid ointment was applied daily to a wound involving 3 per cent of the body area.

the tissues were analyzed for boric acid. The brain showed 212 mg., the liver 107 mg. and the body fat 30 mg. of boric acid per hundred cubic centimeters. The urine values and wound size are plotted in figure 3.

A second dog (206) was treated in an identical fashion after an area of skin measuring 13 by 13 cm. had been removed under pentobarbital sodium anesthesia. It was impossible to prevent the dog from licking the wound, and thus the excretion data were of no value. He was treated daily, however, and at the end of twenty-four days the wound had healed sufficiently to discontinue all boric acid dressings. The urine was then assayed daily until a negative turmeric test was obtained on the fourth day. At autopsy the tissues assayed as follows: wound 103 mg., brain 90 mg., liver 73 mg., kidneys 54 mg. and body fat 39 mg. per hundred cubic centimeters and the urine from the bladder was negative.

On a third dog (213) a third degree burn measuring 11.5 by 11.5 cm. was treated with 50 Gm. daily of boric acid ointment under a pressure bandage. Urine values were determined daily for thirty-three days (fig. 4). At the end of this period the brain showed 247 mg., the liver 18 mg., the fat 60 mg. and the wound tissue itself 60 mg. of boric acid per hundred cubic centimeters.

(*d*) Peritoneal Irrigation with Boric Acid Solution: Two dogs were anesthetized with pentobarbital sodium and a 5 per cent boric acid solution was irrigated through the abdominal cavity for a three hour period by means of an inflow cannula in the region of the liver and an outflow cannula in the left lower flank. The rate of flow was adjusted so that 5 cc. per minute entered the cavity. The perfusate was collected hourly, measured and analyzed for boric acid. At the end of three hours the animals were killed and the tissues analyzed for boric acid. The perfusates showed a drop in boric acid content to approximately 1.5 per cent, and on the basis of the total amount recovered 1 animal retained 34.7 Gm. of boric acid, the other 31.0 Gm. (table 3). The average tissue levels were brain 293 mg., body fat 244 mg. and liver 205 mg. per hundred cubic centimeters.

(*e*) Absorption from the Intact Skin: In order to test absorption from the intact skin 2 male subjects wore regulation navy short sleeve undershirts which were saturated and kept moist for an eight hour period with a 5 per cent aqueous solution of boric acid. Repeated analyses of various specimens up to forty-eight hours failed to demonstrate any boric acid in their urine: The turmeric paper test, which is ordinarily sensitive to 1 part in 5,000, was used. In a second experiment boric acid ointment was applied for six hours to the upper half of the body (neck to waist) of 2 normal male subjects. Individual voidings of urine were again negative for boric acid by the turmeric paper test for the entire twenty-four hour period after application of the ointment. In a third experiment 2 subjects, after voiding, immersed their feet to the ankles in a hot saturated (5 per cent) boric acid solution for periods of thirty and sixty minutes respectively. To avoid contamination the subject was not allowed to touch the foot bath at any time. Urine samples at

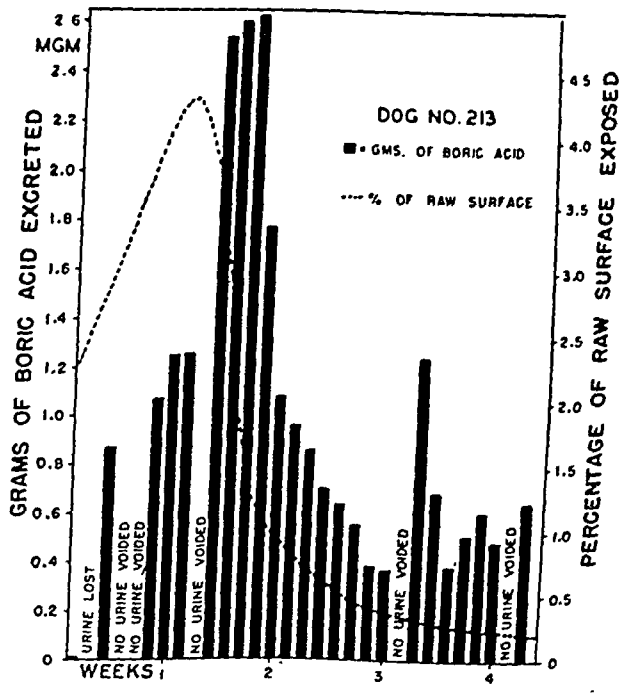

Fig. 4.—Urinary excretion of boric acid for thirty days when boric acid ointment was applied daily to a third degree burn involving 3 per cent of the body area.

one-half, one, three and thirteen hours were negative for boric acid by the turmeric paper test. These samples were alkalized and dried and were found to be almost entirely negative for boron on spectrographic analysis. Only the thirty minute urine samples had very faint boron lines. In the thirty minute urine sample of subject HW the boron line at 2,497 angstroms was

24. Benedict, F. G.: Surface Area Constant in Comparative Physiology, Yale J. Biol. & Med. 4: 385-398 (March) 1932.

slightly less dense than the platinum line at 2,428 angstroms. These densities were reversed in subject CP. Since the only source of platinum was the dish used to ash the urine sample, the amount of platinum and boron in the total ashed specimen can be estimated to be about 10 micrograms. This indicates that the boron

in the original urine sample was in the order of 1 part of boron to 10,000,000 parts of urine.

(*f*) Tissue Levels and Distribution: In an attempt to determine the distribution of boric acid in the tissues, 3 dogs were acutely intoxicated by the administration of 2.0 Gm. per kilogram, and twenty-four to seventy-two hours later analyses of their tissues were made. These results (table 4) show that the brain, the liver and the body fat in the order named are the three organs highest in boric acid content. This fact was confirmed many times in later experiments.

(*g*) Distribution in Fractions of the Brain: Since the studies thus far tended to confirm the findings of previous workers [25] that a large amount of boron accumulated in the brain, an attempt was made to ascertain its distribution within the brain by separating the white from the gray matter. In a dog highly intoxicated with boric acid, whole brain tissue analyzed 214 mg. per hundred cubic centimeters, while the gray matter, obtained by careful slicing with a razor blade, contained 231 mg. per hundred cubic centimeters. The white matter obtained by careful slicing of the corpus callosum contained 142 mg. per hundred cubic centimeters. The data hence indicate a slight preponderance of boric acid in the gray matter. In an attempt to ascertain which chemical fraction of the brain contained most of the boric acid, fresh brains were fractionated for pure phospholipids according to the method of Folch.[22] The brains of 3 dogs and 1 large hybrid polar bear all previously intoxicated with boric acid were used. Each fraction was tested qualitatively for boron and phosphorus by means of the spectrograph. Only the initial acetone extract of brain showed strong boron lines. Although the alcohol and petroleum ether fractions were purified and tested for boron, as well as the remaining residue, none was found. The acetone fraction was further separated into ether soluble and insoluble fractions. The ether insoluble fraction showed the boron lines but none for phosphorus. This fraction was found to be water soluble. The brain of a control animal was fractionated in the same way and showed very faint traces of phosphorus in the same fraction in which boron alone had occurred in the intoxicated animal.

(*h*) Results of Histopathologic Studies: The major pathologic changes in acute boric acid toxicity in mice, rats and dogs involved chiefly the kidney and central nervous system. In all animals there was glomerular and tubular damage. The former consisted of a change in capillary permeability as manifested by glomerular débris in the glomerular spaces in many of the animals. The latter was more serious and involved sometimes pronounced cellular vacuolization, sometimes cellular shedding into the lumen, and nearly always a rich coagulum in the tubule lumens, which in some cases extended into the ducts of Bellini.

In the central nervous system, pathologic changes consisted largely in the presence of an increased number of small cells with dark, round or irregular nuclei (2-4, fig. 5) and in hyperchromatism and shrinkage of certain nerve cells in the spinal cord (5, 6, fig. 5). The small cells are probably microglia. They were most numerous forty-eight hours after injection and were not present in 2 out of 3 brains at seventy-two hours. The density of these small cells was greater with higher dosage and was not closely related to the concentration of boron in the brain at the time of death (table 5). They occurred in 1 case around blood vessels in all layers of

the cortex. In others they seemed to be generally distributed throughout the gray matter of the cortex. In several they appeared clustered around large and small nerve cells, particularly in the deepest layer of the cortex but also in other layers. Sometimes the nerve cells themselves were highly vacuolated, and in one preparation small round cells were present within the cell wall. A moderate reaction took place in the

25. Ross and Conway,[15] McWalter,[20] Willson,[16] Forsythe,[19] Potter,[16] Birch,[10] McNally and Rust.[13]

cortex of 1 dog (204) after boric acid ointment had been applied for one month to an area of the body denuded of skin.

The pronounced hyperchromatism and shrinkage of nerve cells in the spinal cord was observed in the dorsal horn, the intermediate cell column and the ventral horn. The degree of reaction was not closely related to the dosage or to the boron content of the brain at the time of death. Moderate changes were noted in dog 204, whose treatment has been described. The absence of reaction in dog 157, which came to autopsy four days after an oral dose of 1.5 Gm. per kilogram indicates that the reaction of nervous tissue to boron probably persists for only seventy-two hours. Other pathologic changes noted were extensive polymorphonuclear reactions in the subdermal connective tissue layers of the skin. The dermal blood vessels were distended with blood, which may account for the erythema seen in man.

(*i*) Attempts to Antidote Acute Poisoning: Since boric acid combines chemically with polyhydroxyl compounds such as mannitol and glycerol, the administration of these compounds might result in a more rapid excretion (or inactivation) of boric acid and a resultant lessened toxicity. Such an effect should be evidenced by a significant increase in the L. D. 50 Accordingly, mice were injected subcutaneously with toxic doses of boric acid, and various polyhydroxyl compounds were given orally or subcutaneously in the same solution as the boric acid. No antidotal effect, however, was found with any of these compounds. Isotonic solution of three chlorides (combined with plasma or bovine albumin) was strikingly effective as an antidote if given repeatedly in large intravenous doses. These data are summarized in table 6

Figs. 5—Histopathology of the brain and spinal cord following administration of boric acid. COMMENT

With respect to the absolute dosage of boric acid tolerated by the mouse, rat, guinea pig and dog one can state that boric acid is relatively nontoxic. Death is probably due to a combination of vascular depression and central nervous system intoxication. The fact that repeated intravenous injections of isotonic solution of three chlorides and plasma will allow the mouse to tolerate 2.5 times the usual L. D. 50 of boric acid indicates that the most important antidotal measures are those which will counteract circulatory depression and aid in urinary excretion

The increased excretion of phosphorus after intravenous injections may be entirely incidental to tissue injury or it may be due to the chemical release of phosphorus from some compound which has a greater affinity for boron. In support of the latter hypothesis is the occurrence of this phenomenon at a relatively low dosage, the disappearance of the phosphorus lines from the spectrum of that fraction of the brain which absorbs the boron, and the previous findings of Wiley [19] that phosphorus metabolism is definitely disturbed in man during a period of boric acid or borax administration.

The failure of boron to intoxicate the hemopoietic system probably indicates that no portion of the severe anemia which frequently accompanies extensive burns is caused by the treatment of the burns with boric acid ointment.

While the evidence for cumulative action is not incontrovertible, many of the isolated observations in this study indicate that boric acid is definitely a cumulative

poison. These are (1) the long period (fourteen to eighteen days) needed for urinary excretion to reach a plateau, (2) the relatively low forty-eight hour excretion (60 per cent), (3) the characteristics of the urinary excretion curve when boric acid ointment is applied to burns or wounds, (4) the persistence of appreciable amounts of boric acid in the brain and liver of dogs for as long as four days after stopping the daily dose and (5) the accumulation of greater amounts of boron in the brain than that which occurs in the treated wound.

Because of the phosphorus content of phospholipids and the fact that one of the cephalins is known to contain inositol and hence might be expected to absorb boric acid, considerable care was taken to separate the various fractions of the brain. The boron, however, was entirely separated in the first extraction procedure used; namely, drying the brains with acetone. Since boron is also found in large amounts in the body fat, one can postulate that it probably occurs as boroglycerate. Proof of this assumption must await further detailed studies.

The failure of boric acid to appear in the urine when administered as a saturated solution or ointment to the torso of the normal human subject indicates that absorption through the intact skin is negligible. These results are not in agreement with those of Kahlenberg,[26] who detected boric acid in the urine fifty-five to sixty seconds after he immersed his feet in a warm saturated solution. Ochsner [27] also states that boric acid is absorbed through the intact skin. Since three types of experiments designed to favor skin absorption gave negative results by both the turmeric paper test and spectrographic analysis we must conclude that, if skin absorption occurs, the quantity of boron thus taken into the body is negligible and will not result in systemic toxicity.

The degree of expected absorption of boric acid when a saturated solution is used to irrigate a closed cavity has been accurately determined in these studies. Under favorable circumstances the absorption may be as high as 75 per cent of that contained in the irrigating fluid. This definitely prohibits the use of boric acid for that purpose. The washing of granulation tissue for any length of time is probably also highly dangerous.

Boron can be added to that group of elements which are known to affect the central nervous system. These include lead, manganese and arsenic. Compared to these intoxicants boron is much quicker in its action and recovery is also more prompt and apparently more complete. The use of boron as an antiepileptic,[28] which has been advocated from time to time, is probably in accord with the degree of tissue damage attained, but this assumption would have to be confirmed by functional studies in boron intoxicated animals.

SUMMARY

1. Boric acid is absorbed in toxic quantities from ointments applied to burned areas or to wounds involving loss or damage to large areas of skin.

2. When a 5 per cent boric acid solution is used to irrigate cavities, most of the boric acid is absorbed by the tissues.

3. While boric acid is not toxic when administered in a single large dose, repeated doses result in accumulation in the brain, liver and body fat.

4. The boron occurs in both the white matter and gray matter of all parts of the central nervous system and in the peripheral nerves. The spinal cord and gray matter of the cerebrum contain the highest amounts.

5. The liver is only slightly affected histologically by chronic poisoning. The kidney shows tubular degeneration, while the brain and spinal cord show neuronophagia and hyperchromatosis. The skin shows polymorphonuclear infiltration and vascular engorgement.

6. As little as one third the median lethal dose, or treatment of a burn involving only 4 per cent of the surface area of the body with U. S. P. 10 per cent ointment, will produce pathologic changes in the central nervous system.

7. When repeated daily doses as small as 200 mg. per kilogram are given subcutaneously, fourteen to eighteen days are required before urinary excretion reaches a plateau. This, together with the fact that boric acid can still be found in the brain of animals four days after discontinuation of a series of doses, indicates cumulative action.

8. The growth of immature rats is not influenced by 0.1 per cent of boric acid in the drinking water, but a level of 0.25 per cent retards normal growth after twenty days.

9. The data do not provide any evidence of a depressant action of boric acid on the blood forming organs.

10. A definite increase in urinary phosphorus excretion occurs after intravenous doses of boric acid.

11. The boron found in the brain is not combined with phospholipids or cholesterol but is probably present in some simple combination with glycerol or other polyhydroxyl compounds.

12. Death is due to a shocklike syndrome when large doses are given. If moderate dosage is given over a period of several days, death may result from inanition due to convulsive tremors and meningismus. When intravenous fluids are given to prevent early deaths, some animals develop anuria at 2.5 times the untreated median lethal dose.

13. Polyhydroxyl organic compounds such as mannitol, glucose or glycerol are not antidotal to boric acid. Large intravenous doses of isotonic solution of three chlorides and plasma definitely antidote the toxicity.

CONCLUSION

Boric acid, whether applied in the form of an ointment or a saturated solution to extensive wounds, is a cumulative poison. The weak antiseptic value of boric acid suggests that for medicinal use other more active and less potentially harmful therapeutic agents should be employed.

ABSTRACT OF DISCUSSION

DR. CHARLES G. BARNUM, Groton, Conn.: I am reporting the boric acid poisoning of 20 newborn infants in our hospital at New London, Conn. The poisoning was the sequel of the issuing of granular boric acid powder, which looks like dextrose powder, in a jar plainly labeled "Dextrose." When the jar was returned to our formula room the boric acid was made up in isotonic solution of sodium chloride instead of dextrose in saline solution to be used as a prelacteal feeding. The first noted effect came in one infant within eight hours of the time the solution was taken. There was vomiting, diarrhea and a rapidly progressive prostration, which went on to death in about thirty-six hours from the time the first dose was taken. Four other youngsters succumbed. The first clinical effect was vomiting, but the most striking symptom was a tremendous irritation of the central nervous system. The appearance was that of severe meningitis with retraction of the head, opisthotonos,

double Kernig sign, Babinski reflex and rather evident spastic deviation of the eyes. The temperature curves were nearly flat. The urine was scanty and contained little albumin. The amount of prostration was remarkable, with rapid loss of weight due to diarrhea and the failure to take any reasonable amount of fluids. In treatment the fluid requirement was made up with a mixture of isotonic solution of sodium chloride and 5 per cent dextrose solutions given by hypodermoclysis. In the more severely poisoned there was intense generalized redness of the skin, after which the surface came off, as though the youngsters had been superficially burned. The less severely poisoned showed a macular eruption followed by desquamation. The postmortems seemed to indicate that there was a similar extensive inflammation of the mucous membranes. One youngster who survived a good deal longer than the others eventually died of the boric acid poisoning, even though the chemical analysis of the organs showed that the boric acid apparently had been entirely excreted before death. Even to the last the clinical picture was similar to that presented by those who died earlier. The area of exfoliation covered practically the whole surface of the body, even the bottoms of the feet.

DR. HENRY N. HARKINS, Baltimore: In my practice of surgery I see no absolute indication for the use of boric acid in any form whatever. The reports made here today and the discussion bear out once again the toxic dangers of this substance. Would it not be in order to have this section send a recommendation to the Council on Pharmacy and Chemistry that it investigate the possibility and advisability that boric acid be entirely eliminated from all hospitals?

DR. LINCOLN S. OPPER, Norwich, Conn.: There were five deaths in connection with the cases of boric acid poisoning at the New London Hospital. I performed autopsies in 4 cases. Three of the examinations were on 6 to 8 day old infants who had received varying amounts (10 to 13 Gm.) of boric acid in the form of a 5 per cent solution over a period of four days and who succumbed one or two days after the error was recognized and the feedings terminated. The fourth infant lived for sixteen days, having survived the final ingestion of boric acid by eleven days. At autopsy all of the infants showed a more or less extensive generalized rash in the nature of a red exfoliative dermatitis. This has been frequently described in the literature. In the first 3 infants fresh petechial and ecchymotic hemorrhages were noted in the pleural and epicardial surfaces as well as within the thymic tissue. This was thought to be related to anoxia. Focal hemorrhages of considerable size involved the pulmonary parenchyma. Despite superficial erosions of the tongue and despite a diffuse redness of the esophageal mucosa and a few focal areas of fresh hemorrhage in the submucosa of the bowel, the gross changes in the gastrointestinal tract were certainly not impressive. Microscopically the degree of epithelial degeneration and regeneration, particularly of the small intestine, was much more striking. The upper part of the gastrointestinal tract was characterized by an extensive hemorrhagic esophagitis with necrosis and sloughing of large patches of epithelium. In the small intestine, and to a lesser degree in the colon, the cells of the glandular epithelium were very large, with hyperchromatic and bizarre shapel nuclei containing large and prominent nucleoli. Mitotic figures were very numerous. The hemorrhagic cystitis, which was also found in the first 3 cases and which has been commonly described in boric acid deaths, resembled in every way the involvement of the esophagus. The microscopic findings in the liver and kidney were rather disappointing in that the amounts of fat within the cytoplasm of the hepatic and tubular epithelial cells were relatively small and could scarcely be considered pathologic. The brains were all decidedly congested and showed mild cerebellar pressure areas. Blocks of cerebral tissue are being embedded in celloidin to be stained by various neuropathologic technics. In the fourth infant, whose death occurred on the sixteenth day, none of the lesions already described in the gastrointestinal tract and bladder of the first 3 were found. The exfoliative dermatitis was still present in wide distribution, and a bilateral focal pneumonia was noted as the cause of death. Quantitative determinations on the brain or liver of each case revealed 0.52, 0.558 and 0.78 Gm. respectively of boric acid per hundred grams of tissue in the first 3 infants. In those deaths of 6 infants resulting from the accidental ingestion of boric acid which occurred in a Chicago hospital in 1927 the amounts of boric acid recovered from the brain and liver represented approximately a third of our figures. However, the amounts of boric acid taken (saturated solution mistaken for distilled water) were correspondingly smaller. No evidence of boric acid could be demonstrated in the liver of the fourth infant, indicating that the survival time had allowed for complete excretion of the drug.

LIEUTENANT CARL C. PFEIFFER, U.S.N.R.: Dr. Barnum of the New London Hospital had 21 severely poisoned infants, and it can be stated definitely that the mortality in this series of 21 infants was much less than in the instances previously described. Pharmacologically we are definitely handicapped in that there is no animal which has a skin like that of the human being. The skin effects from boric acid poisoning are greater in the case of man, and we do not see as severe pathologic changes in animals. We were glad to have the confirmation of the relative lack of liver damage, which we also found in the animals. We can second the pertinent suggestion of Dr. Harkins that boric acid be discontinued in medicine.

TREATMENT OF NEUROSYPHILIS WITH PENICILLIN

A PRELIMINARY REPORT

DOUGLAS GOLDMAN, M.D.
CINCINNATI

The effectiveness of penicillin in the treatment of syphilis has been clearly demonstrated in early cases by Mahoney[1] and in later cases by Stokes and his group.[2] Early results indicated definite therapeutic benefit. It is to be expected that the drug which is so clearly effective against the treponeme in early cases will be effective as well in the late manifestations of the disease. Advantages which are to be expected in the use of this substance are ease of administration, diffusibility and lack of any serious toxic effects. In this respect it differs widely from all the arsenicals which are in common use.

At Longview State Hospital there is a large group of cases of neurosyphilis available for treatment practically at all times. The admission rate for cases of syphilis varies between 16 and 25 per cent. The average yearly admissions, therefore, for neurosyphilis will be approximately 100 cases. These offer a rather unusual opportunity to study the effects of this very interesting drug in such cases.

For the purpose of the study it was decided to use only patients with dementia paralytica who had unquestionable and typical serologic, spinal fluid and clinical manifestations. Patients with less than typical findings were excluded and were treated with the more common methods. The first 18 cases are presented in this report. In addition a small group of patients with tabes dorsalis was available. Their treatment will be described separately because of its apparent importance in spite of the small number of the group treated. No definite technic for the use of penicillin in syphilis has as yet been established, so this study was initiated with the purpose of trying several technics to determine what results may be reasonably expected from the

---

From Longview State Hospital, Dr. E. A. Baber, superintendent.

This is the initial report of a project for treatment of neurosyphilis with penicillin organized in Ohio State mental hospitals of the Ohio Department of Public Welfare, Dr. F. Tallman, commissioner of mental diseases.

1. Mahoney, J. F.; Arnold, R. C.; Sterner, B. L.; Harris, A., and Zwally, M. R.: Penicillin Treatment of Early Syphilis, J. A. M. A. **126**: 63-67 (Sept. 9) 1944. Mahoney, J. F.; Arnold, R. C., and Harris, A.: Penicillin Treatment of Early Syphilis, Am. J. Pub. Health **33**: 1387-1391 (Dec.) 1943.

methods tried and what modification of the methods tried should be further studied.

In the treatment of the dementia paralytica patients thus far two methods of management were followed. In the first group the patients were given penicillin by a combination of intrathecal and intramuscular injection. The routine established for the purpose of study was as follows: For six days the patients received intrathecal penicillin: on the first two days 10,000 units each day, and on the subsequent four days 20,000 units each day. The technic of making the intraspinal injection, we believe, is of some importance. The penicillin as obtained on the market was dissolved to contain 5,000 units per cubic centimeter; i. e., the 100,000 units was dissolved in 20 cc. of saline solution in the vial in which the penicillin was purchased in the usual manner. Then 2 or 4 cc. of this solution was drawn into a 20 cc. syringe. After the spinal puncture was made and a specimen of spinal fluid for examination was obtained, the syringe was attached to the spinal needle and spinal fluid was drawn slowly to the 20 cc. mark on the syringe. The syringe was then detached and the spinal fluid and penicillin solution thoroughly mixed. Then the mixed penicillin and spinal fluid was reinjected slowly, approximately five minutes being taken

for the injection. The procedure was repeated daily as outlined. During the same period the patient received intramuscular injections of penicillin into the gluteal muscles, 20,000 or 25,000 units being injected every four hours. A total of 900,000 units of penicillin, including the intraspinal injection, was given with the first course. One month after this another series of intramuscular injections alone was given totaling 1,000,000 units, so that the patients received a total of 1,900,000 units altogether. Spinal fluid examinations were made daily during the period of intraspinal injections, one week later and then at the end of thirty, sixty and ninety days to determine changes in the spinal fluid. The patients were not released from the hospital for ninety days, and following this it is projected to observe the patients at three month intervals, including blood and spinal fluid examinations to determine the lasting effectiveness of this form of treatment.

The idea of using intraspinal treatment for neurosyphilis is obviously not new. Swift and Ellis [3] used serum from the patients themselves, drawn immediately after injection of the arsenical. Their method, however, seemed unnecessarily hazardous and burdensome, in spite of frequent brilliant results. The use of penicillin in this manner, on the other hand, is very simple, rapid and completely safe as medical procedures go.

The second group of patients with dementia paralytica was treated with a combination of artificial fever and intramuscular injections of penicillin. The patients were given the routine type of fever treatment used in our hospital, administered by means of the diathermy induction current and an insulating blanket. Temperature records were kept on a recording type of electrical thermometer during the treatment. A total

of approximately thirty hours of fever was given to each patient. This consisted of three sessions of two and one-half to three hours at 105 F. or over each week for a period of four weeks. After the third or fourth fever treatment penicillin 20,000 or 25,000 units every four hours to a total of 1,000,000 units was given. After one month 1,000,000 units was injected in a similar manner without further fever treatment.

Observations made on the patients receiving intraspinal treatments are of some interest. In spite of the large doses of penicillin injected intrathecally no serious local manifestations from the treatment were observed. Eight of 10 patients had fever on one or more days following the intrathecal injection. In every instance the temperature returned to normal before the treatment was completed and remained normal apparently in spite of continued injections of large doses of penicillin. Pleocytosis in the spinal fluid was observed in almost every instance. This was always a transient effect of the drug, although in some instances it was very pronounced. I believe that the proper interpretation of these changes is to consider them a manifestation of so-called therapeutic shock rather than an effect of the penicillin itself. It is well known that any foreign substance, serum or drug will produce increase in the number of cells in the spinal fluid,[4] yet repeated injections of serum will produce repeated

TABLE 3.—*Results of Treatment with Intraspinal Penicillin in Tabes*

increase in cells in the spinal fluid, whereas the injection of penicillin produced only temporary increase which diminished in spite of continued administration of the drug by this route. Similarly the fever seems more fairly ascribed to therapeutic shock than to the effect of penicillin.

All of the patients receiving intraspinal injections of penicillin were allowed up and about the ward except while they had fever and except those patients

4. Goldman, Douglas: Serum Meningitis, Arch. Path. 9: 1027-1037 (May) 1930.

who were too weak and physically disabled from their illness to be allowed this privilege. It is an interesting observation that none of the patients suffered from the so-called spinal puncture headache.

The patients who received fever and penicillin showed no toxic effects whatever from the penicillin. No febrile reaction was observed and there was no evidence of increase in spinal fluid cell counts one week after the treatment. The management of the fever was in no way affected by the use of the penicillin. It seems that the administration of three or four fever treatments before injection of penicillin is an effective means of avoiding therapeutic shock.

The patients used for this study were typical of the state hospital admissions for dementia paralytica. All showed recognizable mental symptoms. They were all in an advanced stage of the disease, many had received irregular treatment over varying periods previous to admission and some had received no treatment at all, as indicated in the summarizing tables. The treatment was administered to 2 patients who were practically moribund, not in the hope of producing benefit but to test the safety of the method. One patient with far advanced tuberculosis who had had a therapeutic pneumothorax maintained for over one year was included in the series.

The 2 aforementioned patients died within ten days following the first series of intraspinal treatments. These had been in a state of pronounced physical and mental deterioration before treatment was started and were to be considered tests of safety rather than hopeful attempts at treatment. This in itself is an interesting point, since among a group of deteriorated patients suffering from dementia paralytica 10 to 20 per cent may be expected to die within three months following admission to a state hospital, regardless of their manner of treatment. Some degree of clinical improvement is manifested in practically every one of the remaining patients. Eight cases show evidence of rapid remission which can be expected to lead to complete recovery within a short time. Nine others have shown within the period of observation improvement of varying degree which is sufficiently definite to justify an optimistic outlook for eventual recovery. The only complete failures in the series were the patients who failed to survive. The results in the patients treated with fever and penicillin are practically similar to those in the patients treated with the combination of intraspinal and intramuscular penicillin. A number of the latter, however, were certainly in no fit condition to have fever treatment and would have been considered hopeless for any other means of therapy than the one employed.

Whether this method of treatment with the doses outlined is to be considered the most effective procedure must be settled by longer observation. It is quite likely that the ideal method of treatment of such patients will be by means of multiple procedures, perhaps larger amounts of penicillin and fever. Arsenicals and bismuth are being withheld from this group of patients because (1) improvement seems adequate or better thus far and (2) the results of the single drug should not be obscured.

TABES DORSALIS

The treatment of the patients with tabes dorsalis is particularly interesting. Four such patients were treated, 2 from the hospital and 2 from private practice. Two of the patients showed as their chief manifestations tabetic crises with pronounced abdominal and other sensory root symptoms. In 1 patient the crises were of such severity that she had been committed to the hospital not for syphilis but for a deep suicidal depression which resulted from the severity of her pain. These recurred at intervals of approximately thirty days and lasted from five to twelve days more or less in each bout. The other patient was one who had had more or less chronic pains which had become unendurable for a long period. Both of these patients had had intense antisyphilitic treatment over a long period and were considered well otherwise.

The other 2 patients with tabes were patients who showed typical motor manifestations of ataxia of the lower extremities. These patients had also received large amounts of treatment by means of fever, arsenicals and bismuth, with apparent arrest of the symptoms but certainly inadequate improvement in the chief manifestation of the disorder.

The patients suffering from tabes were treated with intrathecal penicillin only. The method of administration was the same as that used for the dementia paralytica patients. Six daily injections were made with a total of 100,000 units of penicillin. No other treatment was given at the same time. Patient A. B. was further treated with aldarsone beginning one week after the treatment.

The period of observation on the ataxic patients is considered too brief as yet to be conclusive. A certain amount of definite improvement, however, is clearly manifested in at least 1 of these. The patients who suffered tabetic crises, however, showed improvement that was almost immediate and is apparently of an enduring nature. The patient with the worst pain, who had been suicidal because of its severity, has had no recurrence of symptoms for a period of approximately three months in spite of the occurrence of acute pyelitis during this period. The pyelitis responded in the usual way to sulfonamide drugs and was associated with no excessive pain. This woman's personality has changed to one of normal warmth and brightness from its previous distracted depression. The other patient has also enjoyed remarkable relief from pain. The improvement is less striking only because the pain was not so dramatic to begin with. In these patients also the period of observation is too brief to be conclusive for the establishment of a technic, particularly with regard to dosage and frequency of administration of the drug.

CONCLUSION

1. Eighteen patients with dementia paralytica and 4 patients with tabes dorsalis were treated with penicillin.
2. Patients with dementia paralytica were divided into two groups, one of which was treated with a combination intraspinal and intramuscular penicillin, the other with fever and intramuscular penicillin alone.
3. With only 2 exceptions definite clinical improvement occurred in all of the patients in this group. Some of these are apparently recovering rapidly from their disease.
4. The spinal nerve root pains of tabes are apparently rapidly relieved by intraspinal administration of penicillin.
5. Only 2 patients of the entire series died within a short period after the treatment, and these were practically moribund with strong physical and neurologic evidence of deterioration previous to treatment.
6. Early results are sufficiently favorable to justify continued study of the treatment of neurosyphilis with penicillin by various technics.

THE LOW AGGLUTININ TITER OF BOTH SMALL AND LARGE POOLS OF PLASMA

WILLIAM THALHIMER, M.D.
Associate Technical Director, Blood Donor Service, American Red Cross
NEW YORK

AND

MAJOR EARL S. TAYLOR
Technical Director, Blood Donor Service, American Red Cross
MEDICAL CORPS, ARMY OF THE UNITED STATES

WITH THE TECHNICAL ASSISTANCE OF
MRS. THELMA S. SHAUB

It is well known that when plasmas obtained from individuals belonging to the different blood groups are pooled there is evident neutralization of the agglutinins in the pooled plasma. This neutralization of the agglutinins occurs between A and B agglutinogens present in solution in the plasma from groups A, B and AB and the anti-A and anti-B agglutinins from groups O, A and B.

The agglutinin titers in pooled plasma are believed to be sufficiently low so that pooled plasma can be administered intravenously in large amounts to individuals of any blood type without fear of causing serious reactions from possibly incompatible agglutinins.[1] This is borne out by an extensive, worldwide experience by a great number of physicians in the therapeutic intravenous use of pooled plasma.

However, when this investigation was started there were no publications of the determination of the agglutinin titers in large numbers of pools of plasma as they are being prepared for use by the armed forces and in civilian practice. In fact, there was no generally accepted single technic for isoagglutinin titration. Some observers read the tests macroscopically and some with low power microscope magnification. Some carry out the tests on regular microscope slides, some in test tubes. Some centrifuge the test tubes before reading, some do not. The time factor before reading the test varies from a few minutes (with the centrifuge technic) to two hours. Temperature varies also, although most tests are carried out at "room temperature." Consequently it has been impossible to compare titrations by different workers using different technics, and this will continue until a standardized method is adopted by all.

At present there appears to be a trend for every one to use a macroscopic test tube technic similar to that described here. This method is simple, requires only simple apparatus, such as test tubes and pipets, is accurate and can be performed by any competent laboratory technician. It is the method of choice when only a few plasmas or serums must be titrated. It becomes arduous when large numbers of samples are to be examined, and for large scale use the large slide method is to be recommended.

This report is based on the determination of the anti-A and anti-B agglutinin titers in liquid samples of 1,354 pools of plasma. (Most of these pools represented by these samples were shell frozen and dried.)

Nine hundred and ninety-eight samples were obtained from eight processing laboratories during their routine preparation of pools of plasma for the armed forces, from citrated blood obtained through the Blood Donor Service of the American Red Cross. One hundred and forty-two samples were obtained from the Surgical Physiology Division, Army Medical School, and 209 samples from the Blood and Plasma Department, Naval Medical School.

These samples were obtained at random as the plasma was being processed, or occasionally samples from every fifth or tenth pool were taken. In the processing laboratories, therefore, these represent random samples from an extremely large number of pools, and a very considerable number of pools from the Surgical Physiology Division, Army Medical School, and the Naval Medical School. There also was no selection of blood groups of the individual plasmas which went into each of these pools; the plasmas were pooled as they came to the laboratory.

METHODS

The titrations were carried out by a large glass slide method,[2] and the readings were made macroscopically. This method was checked repeatedly with the test tube method as used by the Surgical Physiology Division, Army Medical School,[3] and macroscopic readings with both were found to check practically always within one dilution. Duplicate tests with both methods also checked practically always within one dilution. This is the limit of accuracy of both methods.

With this large slide method one can also use an end point by examination under the low power of the microscope. This modification is described so that it may be used for comparison with other methods using a similar end point. We have compared this with Davidsohn's method,[4] in which the end point is determined under the low power of the microscope, and found the titers by both methods to check within one dilution. The low power microscope titers are always one or two dilutions higher than the naked eye titers, and this should be taken into consideration in comparing the two.

However, we recommend that only the macroscopically determined titer be utilized, since it checks well with the test tube method, also read macroscopically.

LARGE GLASS SLIDE METHOD FOR DETERMINING THE AGGLUTININ TITER[5]

1. The A and B cells used in determining the titer of a serum must be of average sensitivity. This is determined by testing the cells of several individuals against a serum or plasma of low titer, using ascending dilutions of the low titer serum. Dilutions of the serum should be in arithmetical progression (1:10, 1:20, 1:30 and so on). It will be found that the end point will vary with the same serum with different cells. The spread may be, for example, from 1:10 to 1:50. In such a case cells showing an end point at approximately 1:30 may be considered of average sensitivity.

A sufficient amount of blood may be taken from a satisfactory donor for one week's work and placed in enough sodium citrate solution to prevent clotting. These cells must be kept refrigerated and a sufficient amount for the day's work removed each morning and washed three times with an 0.85 per cent solution of sodium chloride.[6]

3. Lozner, E. L., and Newhouser, L. R.: Preservation of Normal Human Plasma in the Liquid State: Studies on Isohemagglutinin Titers, J. Clin. Investigation **23**: 361-363, 1944.

4. Davidsohn, I.: Test for Infectious Mononucleosis, Am. J. Clin. Path. (Tech. Supp.) **2**: 56-60, 1938.

5. This method can be used with accuracy for determining blood types in large numbers of individuals.

6. Usually fresh cells from the same individuals were used.

A 1 or 2 per cent suspension of the cells in an 0.85 per cent solution of sodium chloride should be used for the titration.

2. Final dilutions of the plasma or serum should be made as follows: 1:10, 1:20, 1:40, 1:80, 1:160 and so on (or 1:2, 1:4, 1:8 and so on).

3. The dilutions recorded should be actual dilution of the serum used in the individual tests.

4. The same pipet is used throughout a single test. The most convenient is an eyedropper with a rubber nipple. This will insure all drops being of the same size. Care must be taken to rinse the pipet thoroughly with an 0.85 per cent solution of sodium chloride each time a different solution or different dilution is used.

5. The tests are performed on large plate glass slides, 4 by 10 inches in size, ruled off in 1 inch squares with a wax pencil. The drops of plasma or serum and the suspension of cells are placed in the center of each square. The mixture on each square consists of one drop of original or diluted plasma or serum, one drop of a 1 per cent suspension of cells that have been washed three times in isotonic solution of sodium chloride and one drop of isotonic solution of sodium chloride. The addition of the drop of saline solution has been found to increase the accuracy of the test and prevents drying before the tests are read. (We have corrobrated the findings of Wiener that this small amount of dilution caused by the additional drop of saline solution does not influence the determination of the titer of the plasma. The amount of agglutinin added is the determining factor, and it takes at least six or seven times dilution with added saline solution to influence the degree of agglutination in each individual test.)
